Report of the ICES Advisory Committee
(Revised 15 May)

NORTH ATLANTIC SALMON STOCKS

Introduction

Main tasks

At its 2019 Statutory Meeting, ICES resolved (C. Res. 2019/2/FRSG17) that the Working Group on North Atlantic Salmon (WGNAS; chaired by Martha Robertson, Canada) will meet 24 March–2 April 2020 in Copenhagen, Denmark. Due to the coronavirus disease (COVID-19), the working group met via web conference to address questions posed to ICES by the North Atlantic Salmon Conservation Organization (NASCO).

The table below identifies the sections of the report that provide response to the questions posed by NASCO in the Terms of Reference (ToR).

ToR	Question	Section
1	With respect to Atlantic salmon in the North Atlantic area:	sal.oth.nasco
1.1	provide an overview of salmon catches and landings by country, including unreported catches, catch-and-release, and production of farmed and ranched Atlantic salmon in 2019[1];	
1.2	provide a compilation of tag releases by country in 2019.	
2	With respect to Atlantic salmon in the North-East Atlantic Commission area:	sal.neac.all
2.1	describe the key events of the 2019 fisheries[2];	
2.2	review and report on the development of age-specific stock conservation limits, including updating the time-series of the number of river stocks with established CLs by jurisdiction;	
2.3	describe the status of the stocks, including updating the time-series of trends in the number of river stocks, meeting CLs by jurisdiction.	
3	With respect to Atlantic salmon in the North American Commission area:	sal.nac.all
3.1	describe the key events of the 2019 fisheries (including the fishery at Saint Pierre and Miquelon)[2];	
3.2	update age-specific stock conservation limits based on new information as available, including updating the time-series of the number of river stocks with established CLs by jurisdiction;	
3.3	describe the status of the stocks, including updating the time-series of trends in the number of river stocks, meeting CLs by jurisdiction.	
4	With respect to Atlantic salmon in the West Greenland Commission area:	sal.wgc.all
4.1	describe the key events of the 2019 fisheries[2];	
4.2	describe the status of the stocks[3].	

[1] With regard to question 1.1 for the estimates of unreported catch, the information provided should, where possible, indicate the location of the unreported catch in the following categories: in-river, estuarine, and coastal. Numbers of salmon caught and released in recreational fisheries should be provided.

[2] In the responses to questions 2.1, 3.1, and 4.1, ICES is requested to provide details of catch, gear, effort, composition, and origin of the catch and rates of exploitation. For homewater fisheries, the information provided should indicate the location of the catch in the following categories: in-river, estuarine, and coastal. Information on any other sources of fishing mortality for salmon is also requested (for 4.1, if any new phone surveys are conducted, ICES should review the results and advise on the appropriateness for incorporating resulting estimates of unreported catch into the assessment process).

[3] In response to question 4.2, ICES is requested to provide a brief summary of the status of North American and Northeast Atlantic salmon stocks. The detailed information on the status of these stocks should be provided in response to questions 2.3 and 3.3.

In response to the Terms of Reference, WGNAS considered 25 working documents. A complete list of acronyms and abbreviations used in this report is provided in Annex 1. References cited are indicated in Annex 2.

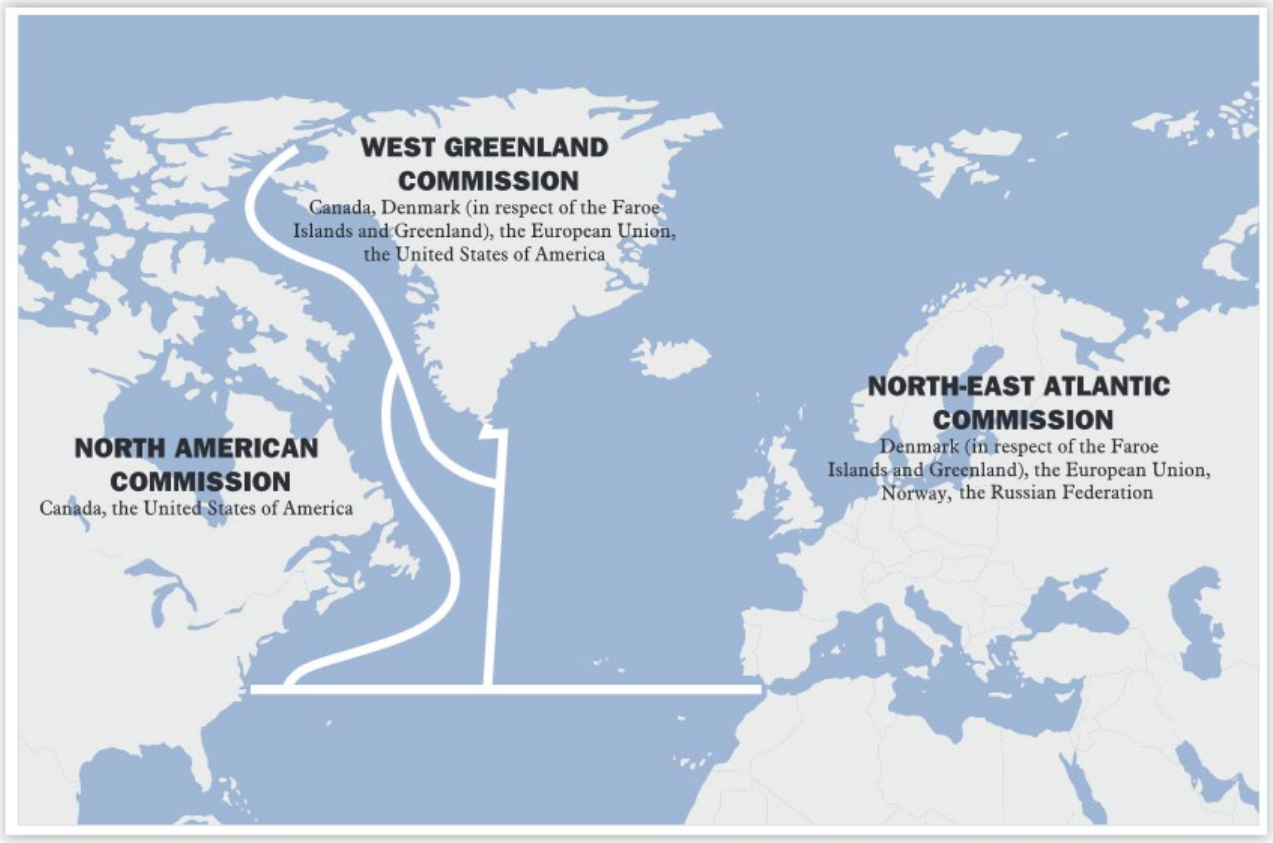
Please note that for practical reasons, Tables 5–8 are found at the end of this document on pages 13–22, immediately preceding the annexes.

Management framework for salmon in the North Atlantic

This advice has been produced by ICES in response to the Terms of Reference posed by the North Atlantic Salmon Conservation Organization (NASCO), pursuant to its role in international management of salmon fisheries. NASCO was set up in 1984 by international convention (the Convention for the Conservation of Salmon in the North Atlantic Ocean), with a responsibility for the conservation, restoration, enhancement, and rational management of wild salmon in the North Atlantic. Although sovereign states retain their role in the regulation of salmon fisheries for salmon originating from their

own rivers, distant-water salmon fisheries, such as those at Greenland and the Faroe Islands, which take salmon originating from rivers of another party, are regulated by NASCO under the terms of the Convention. NASCO has six Parties at present that are signatories to the Convention, including the EU, representing its Member States.

NASCO's three commission areas, the North American Commission (NAC), the West Greenland Commission (WGC), and the North-East Atlantic Commission (NEAC), are shown in the map below. The islands of Saint Pierre and Miquelon (French territory in North America), located off the south coast of Newfoundland, are not part of the NAC, but France (in respect of Saint Pierre and Miquelon) participates as an observer to NASCO. The mid-Atlantic area is not covered by any of the three NASCO commissions; however, under Article 4 of the NASCO Convention, NASCO provides a forum for consultation and cooperation on matters concerning the salmon stocks in this area.



Management objectives

NASCO's objective is:

"..to contribute through consultation and co-operation to the conservation, restoration, enhancement, and rational management of salmon stocks… taking into account the best scientific evidence available…".

NASCO further stated that "the Agreement on the Adoption of a Precautionary Approach states that an objective for the management of salmon fisheries is to provide the diversity and abundance of salmon stocks", and NASCO's Standing Committee on the Precautionary Approach interpreted this as having "to maintain both the productive capacity and diversity of salmon stocks" (NASCO, 1998).

NASCO's Action Plan for Application of the Precautionary Approach (NASCO, 1998) provides an interpretation of how this is to be achieved:

- "Management measures should be aimed at maintaining all stocks above their conservation limits by the use of management targets".

- "Socio-economic factors could be taken into account in applying the precautionary approach to fisheries management issues".
- "The precautionary approach is an integrated approach that requires, *inter alia*, that stock rebuilding programmes (including as appropriate, habitat improvements, stock enhancement, and fishery management actions) be developed for stocks that are below conservation limits".

Reference points and application of precaution

Atlantic salmon has characteristics of short-lived fish stocks; mature abundance is sensitive to annual recruitment because the adult spawning stock consists of only few age groups. Incoming recruitment is often the main component of the fishable stock. For such fish stocks, ICES maximum sustainable yield (MSY) approach is aimed at achieving a target escapement (MSY $B_{escapement}$, the minimum amount of biomass left to spawn). No catch should be allowed unless this escapement can be achieved. The escapement level should be set such that there is a low risk of future recruitment being impaired.

For salmon, this approach has led to defining river-specific conservation limits (CLs), as equivalent to MSY $B_{escapement}$. ICES considers that to be consistent with the MSY and the precautionary approach, fisheries should only be carried out on salmon from rivers where stocks have been shown to be at full reproductive capacity. Furthermore, due to differences in the status of individual stocks within stock complexes, mixed-stock fisheries present particular threats.

In many counties/jurisdictions, CLs are now defined, using stock–recruitment relationships and the corresponding CLs are not updated annually. In other jurisdictions, where such relationships are not available, stock–recruitment proxies are used to define the CLs and these may vary from year-to-year as new data are added. NASCO has adopted the CLs as limit reference points (NASCO, 1998). CLs are used in reference to spawners. When referring to abundance prior to fisheries in the ocean (pre-fishery abundance, PFA), the CLs are adjusted to account for natural mortality, and the adjusted value is referred to as the spawner escapement reserve (SER).

Management targets have not yet been defined for all North Atlantic salmon stocks. Where there are no specific management objectives, the MSY approach shall apply:

- ICES considers that if the lower bound of the 90% confidence interval of the current estimate of spawners is above the CL, then the stock is at full reproductive capacity (equivalent to a probability of at least 95% of meeting the CL).
- When the lower bound of the confidence interval is below the CL, but the midpoint is above, then ICES considers the stock to be at risk of suffering reduced reproductive capacity.
- Finally, when the midpoint is below the CL, ICES considers the stock to suffer reduced reproductive capacity.

For catch advice on the mixed-stock fishery at West Greenland (catching non-maturing one-sea-winter (1SW) fish from North America and non-maturing 1SW fish from Southern NEAC [NEAC–S]), NASCO has, as part of an agreed management plan, adopted a risk-based approach with a 75% probability of simultaneous attainment of management objectives in seven assessment regions (ICES, 2003). NASCO uses the same approach for catch advice for the mixed-stock fishery, affecting six assessment regions for the North American stock complex. ICES notes that the choice of a 75% probability of simultaneous attainment in six or seven stock assessment regions is approximately equivalent to a 95% probability of attainment in each individual unit (ICES, 2013).

There is no formally agreed management plan for the fishery at the Faroe Islands. However, ICES has developed a risk-based framework for providing catch advice for fish exploited in this fishery (mainly multi-sea-winter (MSW) fish from NEAC countries). Catch advice is provided at both the stock complex and country level, with catch options tables providing the probability of meeting CLs in the individual stock complexes or countries, as well as in all the stock complexes or countries simultaneously. ICES has recommended (ICES, 2013) that management decisions should be based principally on a 95% probability of attainment of CLs in each stock complex/country individually. The simultaneous attainment probability may also be used as a guide, but managers should be aware that this probability will generally be quite low when large numbers of management units are used.

NASCO 1.1 Catches of North Atlantic salmon

Nominal catches of salmon

In this document, catches are equivalent to harvest (i.e. removals) and do not include released fish in the recreational fishery. Details on the catches are reported in Tables 5–7. Caught and released fish are reported separately in Table 8.

Reported total nominal catches of salmon in four North Atlantic regions from 1960 to 2019 are shown in Figure 1. Nominal catches reported by country are provided in Table 5. Catch statistics in the North Atlantic include fish-farm escapees, and in some Northeast Atlantic countries also ranched fish. The reported total nominal catch for 2019 was 868 tonnes, the lowest in the time-series.

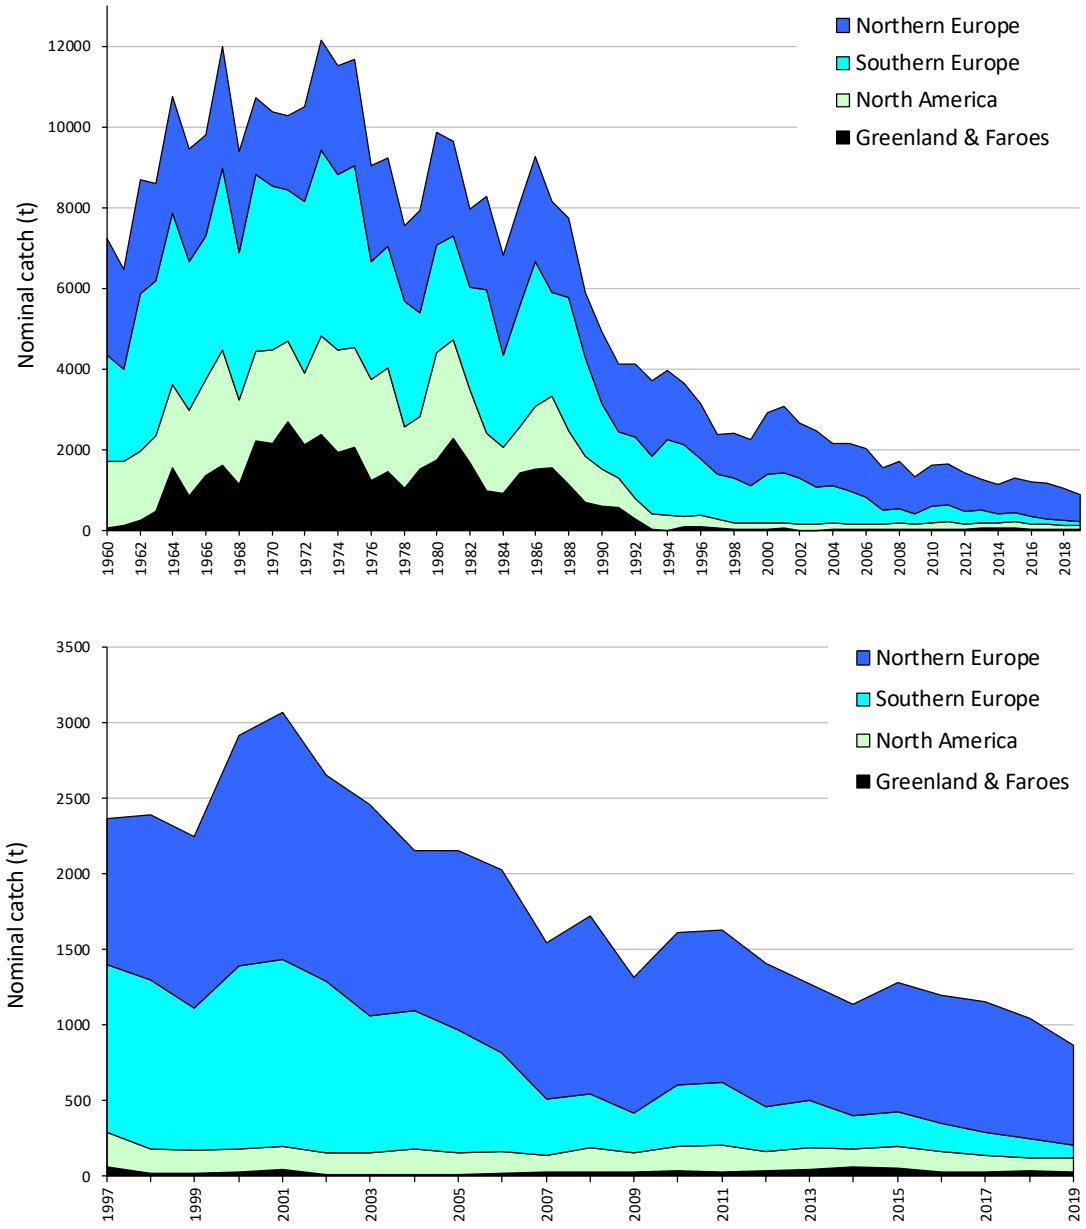


Figure 1 Total reported nominal catch of salmon (tonnes round fresh weight) in four North Atlantic regions, 1960–2019 (top) and 1997–2019 (bottom).

Icelandic catches have traditionally been separated into wild and ranched, reflecting the fact that Iceland has been the main North Atlantic country where large-scale ranching has been undertaken, with the specific intention of harvesting all returns at the release site and with no prospect of wild spawning success. The release of smolts for commercial ranching

purposes ceased in 1998 in Iceland, but ranching for angling fisheries in two Icelandic rivers continued into 2019 (Table 5). Catches in Sweden are also separated into wild and ranched over the entire time-series. The latter fish represent adult salmon, originating from hatchery-reared smolts that have been released under programmes to mitigate hydropower impacts. These fish are also exploited very heavily in home waters and have no possibility to spawn naturally in the wild. While ranching does occur in some other countries, it is on a much smaller scale. The ranched components in Iceland and Sweden have therefore been included in the nominal harvest.

Table 1 Reported catches (in tonnes) for the three NASCO commission areas for 2010–2019, including some updated values.

Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
NEAC	1414	1419	1250	1080	954	1081	1028	1011	927	743
NAC	156	182	129	143	122	144	140	113	80	95
WGC	40	28	33	47	58	57	27	28	40	30
Total	1610	1629	1412	1269	1134	1282	1195	1152	1047	868

NASCO requested that the nominal catches in homewater fisheries be partitioned according to whether the catch is taken in coastal, estuarine, or in-river fisheries (Table 2).

Table 2 The 2019 nominal catches (in tonnes) for the NEAC and NAC commission areas.

Area	Coastal		Estuarine		In-River		Total
	Weight	%	Weight	%	Weight	%	Weight
NEAC 2019	241	32	24	3	478	64	743
NAC 2019	8	9	38	40	49	51	95

Coastal, estuarine, and in-river catch data aggregated by Commission area are presented in Figure 2. In Northern NEAC (NEAC–N), an increasing proportion and weight of the nominal catch was taken in coastal fisheries from 2015 to 2018, followed by a decrease in 2019. There are no coastal fisheries in Iceland, Denmark, or Finland. At the beginning of the time-series, about half the catch was reported from coastal fisheries and half from in-river fisheries, whereas since 2008, coastal fisheries catches represent around 30–40% of the total. In NEAC–S, coastal fisheries made up the largest component of the catch until 2009. Since then, the majority of the catch has been from in-river fisheries, reflecting widespread measures to reduce exploitation. There was no coastal catch in NEAC–S in 2019. In NAC, two-thirds of the total catch has been reported from in-river fisheries, except in 2018 and 2019, when it was about half of the total catch; the catch in coastal fisheries has been relatively small throughout the time-series (13 tonnes or less).

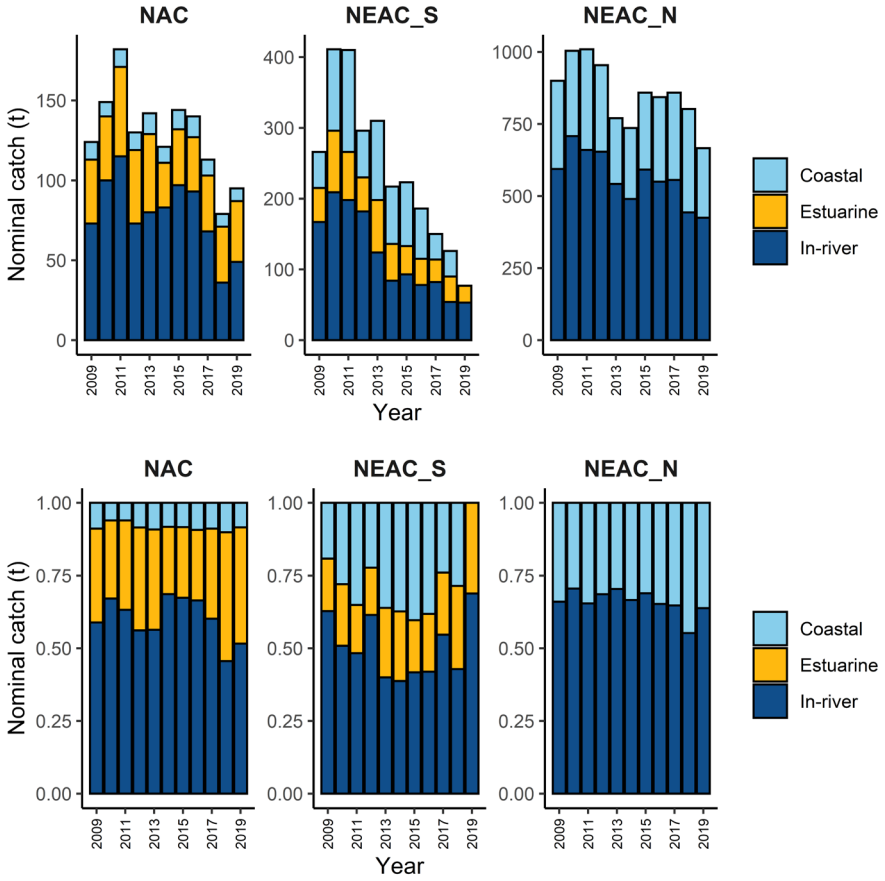

Figure 2 Nominal catches (tonnes; top panels) and percentages of the nominal catches (bottom panels) reported from coastal, estuarine, and in-river fisheries for the NAC area, and for the Northern (NEAC–N) and Southern (NEAC–S) NEAC areas, 2009–2019. Note that scales of vertical axes in the top panels vary.

There is considerable variability in the distribution of the catch among individual countries (Figure 3 and Table 6). In most countries, the majority of the catch is now reported from in-river fisheries and, across the time-series, the coastal catches have declined markedly. However, nominal catches from in-river fisheries have also declined in many countries as a result of increasing use of catch-and-release in angling fisheries.

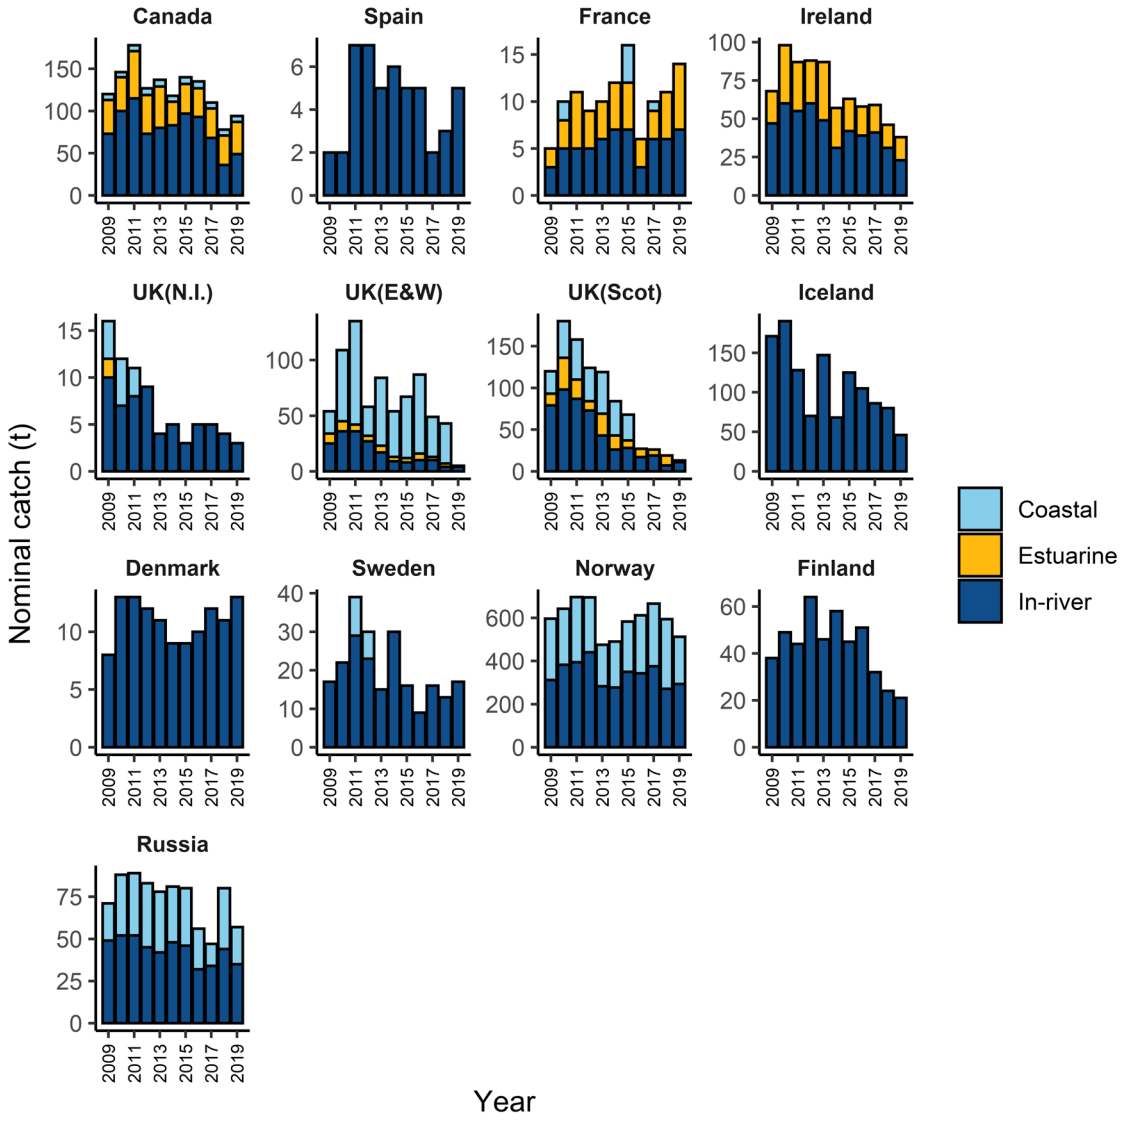

Figure 3 Nominal catch (tonnes) by country taken in coastal, estuarine, and riverine fisheries, 2009–2019. Note that scales on the *y*-axes vary. The USA is not included because there has been no catch. 100% of the fishery at Saint Pierre and Miquelon and at West Greenland occurs in coastal areas. These catches are not shown.

Unreported catches

The total unreported catch in NASCO areas in 2019 was estimated at 258 tonnes. No estimates were provided for Russia, France, Spain, or St Pierre and Miquelon in 2019. The unreported catch in the NEAC area in 2019 was estimated at 237 tonnes, and for the West Greenland and North American commission areas at 10 tonnes and 12 tonnes, respectively.

Table 3 Unreported catch (in tonnes) by NASCO Commission area in the last ten years.

Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
NEAC	357	382	363	272	256	298	298	318	279	237
NAC	26	29	31	24	21	17	27	25	24	12
WGC	10	10	10	10	10	10	10	10	10	10
Total	393	421	403	306	287	325	335	353	313	258

The 2019 unreported catch by country is provided in Table 7. Unreported catch data were not provided by category (coastal, estuarine, and in-river). Over recent years, efforts have been made to reduce the level of unreported catch in a number of countries.

Catch-and-release

The practice of catch-and-release (C&R) in angling fisheries has become increasingly common as a salmon management/conservation measure in light of the widespread decline in salmon abundance in the North Atlantic. In some areas of Canada and USA, C&R became widely applied as a management measure in 1984, and in recent years it has been introduced in many European countries, both as a result of statutory regulation and through voluntary practice.

The nominal catches do not include salmon that have been caught and released. Table 8 presents C&R information from 1991 to 2019 for countries that provide records; C&R may also be practised in other countries, while not being formally recorded. There are large differences in the percentage of the total angling catch that is released. In 2019, it ranged from 20% in Sweden and Norway to 92% in UK (Scotland), reflecting varying management practices and angler attitudes among countries. Within countries, the percentage of released fish has increased over time. There is also evidence from some countries that larger MSW fish are released in higher proportions than smaller fish. Overall, more than 162 000 salmon were reported to have been released in the North Atlantic area in 2019.

Farming and sea ranching of Atlantic salmon

The provisional estimate of farmed Atlantic salmon production in the North Atlantic area for 2019 was 1 750 000 tonnes (Figure 4). The production of farmed salmon in this area has exceeded one million tonnes since 2009. Norway and UK (Scotland) continue to produce the majority of the farmed salmon in the North Atlantic (78% and 11%, respectively). Farmed salmon production in 2019 was above the previous five-year mean in all countries, with the exception of Canada (production in 2018 estimated from 2017 data) and Spain. Spain reported its production of farmed salmon to ICES with a time-series from 2015 (no data for 2018): production in 2019 was 12 tonnes and the maximum was 25 tonnes in 2017. Data for UK (Northern Ireland) since 2001 and data for the east coast of US are not publicly available; this is also the case for some regions within countries in some years.

Worldwide production of farmed Atlantic salmon has been in excess of one million tonnes since 2001 and over two million tonnes since 2012. The worldwide production in 2019 is provisionally estimated at 2 504 000 tonnes (Figure 4), which is higher than in 2018 and the previous five-year mean (2 332 000 tonnes). Production outside the North Atlantic is estimated to have accounted for one-third of the total worldwide production in 2019, dominated by Chile (81%).

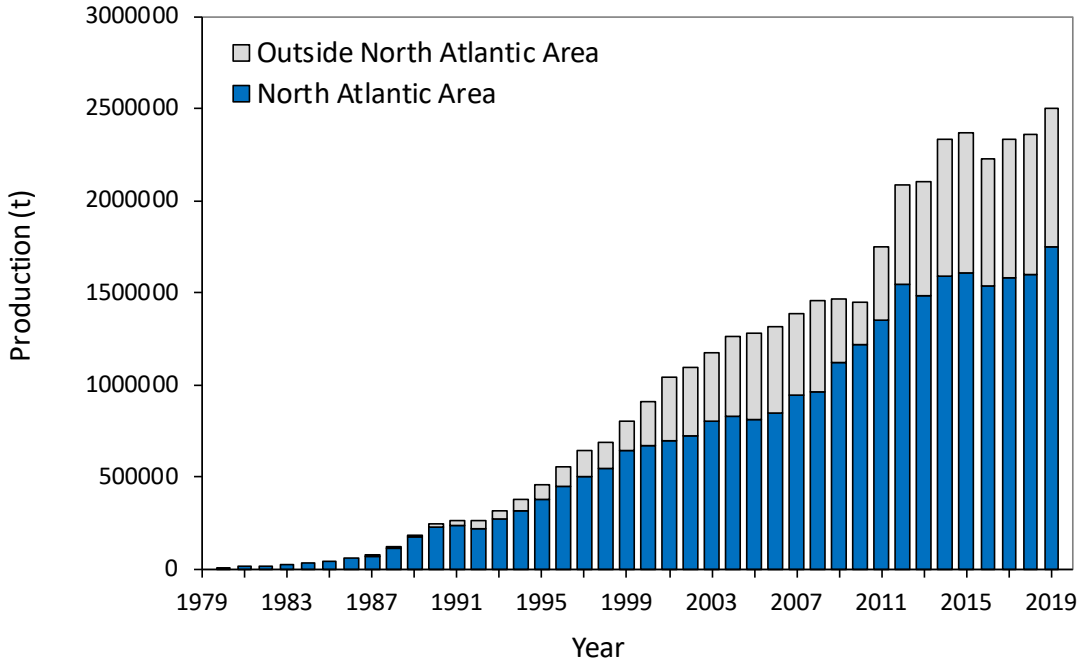

Figure 4 Worldwide production of farmed Atlantic salmon, 1980 to 2019.

The reported nominal catch of Atlantic salmon in the North Atlantic was in the order of 0.03% of the worldwide production of farmed Atlantic salmon in 2019.

The total harvest of ranched Atlantic salmon in countries bordering the North Atlantic was 26 tonnes in 2019, all taken in Iceland (14.8 tonnes), Sweden (7.7 tonnes), and Ireland (3.6 tonnes; Figure 5). No estimate was made of the ranched salmon production in Norway, as catches have been very low in recent years (< 1 tonne), or in UK (Northern Ireland), where the proportion of ranched fish has not been assessed since 2008.

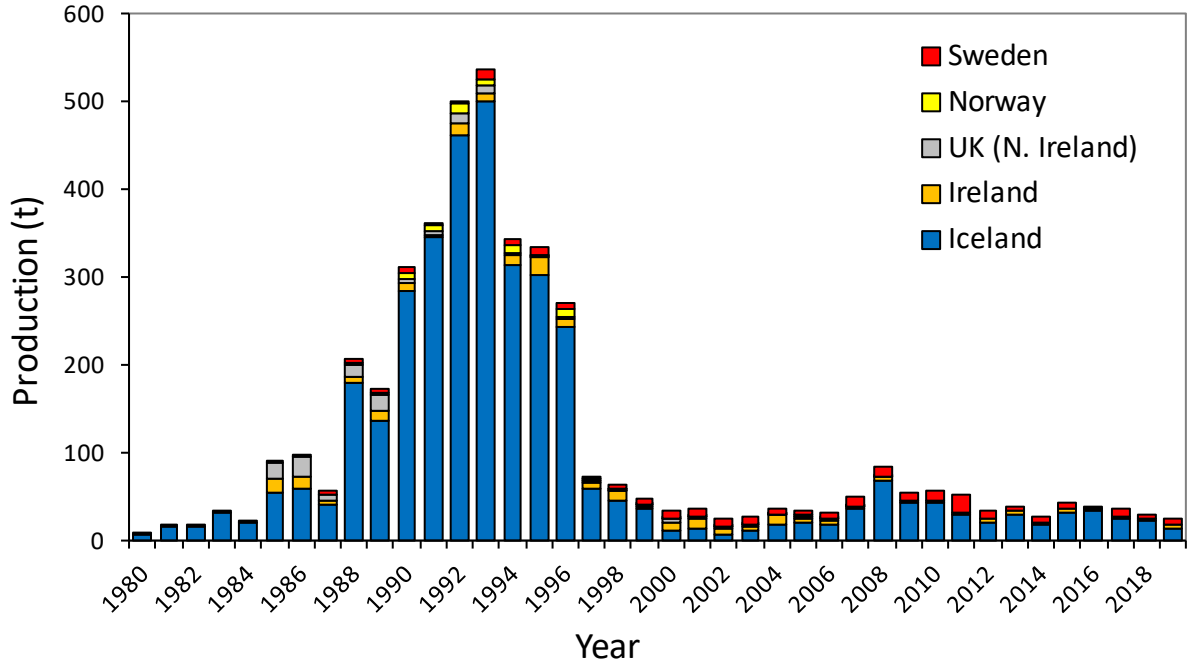

Figure 5 Harvest of ranched Atlantic salmon (tonnes round fresh weight) in the North Atlantic, 1980–2019.

NASCO 1.2 Provision of a compilation of tag releases by country in 2019

Data on releases of tagged, fin-clipped, and other marked salmon in 2019 are compiled as a separate report (ICES, 2020). In summary (Table 4):

- Approximately 2.2 million salmon were marked in 2019, reduced from the 2.7 million salmon marked in 2018.
- The adipose clip was the most commonly used primary marker (1.73 million), with coded wire microtags (CWT) (0.282 million) being the next most common primary marker.
- Most marks or tags were applied to hatchery-origin juveniles (2.08 million), while 13 933 hatchery adults, 93 165 wild juveniles, and 6629 wild adults were also marked.
- The use of PIT tags, data storage tags (DSTs), and radio and/or sonic transmitting tags (pingers) has increased in recent years. In 2019, 161 705 salmon were tagged with these tag types (Table 4), an increase from the number in 2018 (135 157 salmon). ICES noted that not all electronic tags were being reported in the tag compilation. Tag users should be encouraged to include these tags or tagging programmes in the tag compilation, as it greatly facilitates identification of the origin of tags recovered in fisheries or tag-scanning programmes in other jurisdictions. A previous section (PIT tag-screening programmes) recommends the creation, on a European scale, of a database recording, and programmes using, PIT tags.

Since 2003, ICES has reported information on markers being applied to farmed salmon to facilitate tracing the origin of farmed salmon captured in the wild in the case of escape events. In the US, genetic "marking" procedures have been adopted where broodstock are genetically screened. The resulting database is used to match genotyped escaped farmed salmon to a specific parental mating pair and subsequent hatchery of origin, stocking group, and marine site from which the salmon escaped. This has also been applied in Iceland: in the 2018 and 2019 fisheries, 15 out of 18 farmed escapees could be traced to the pens they escaped from, by matching their genotypes to known parental genotypes, and a further two could be traced to foreign broodstocks.

Table 4 Summary of the number of Atlantic salmon tagged and marked in 2019 – "Hatchery" and "Wild" juvenile refer to smolts and parr.

Country	Origin	Primary tag or mark			Other internal[1]	Total

Key:

1. Includes estimates of some local sales and prior to 1984, bycatch.
2. Saint Pierre and Miquelon is a self-governing territorial overseas collectivity of France, located in North America, off the south coast of Newfoundland.
3. Before 1966, sea trout and sea charr were included (5% of total).
4. Values from 1991 to 2000 do not include catches taken in the recreational (rod) fishery.
5. From 1990, catch includes fish ranched for both commercial and angling purposes.
6. Catches from hatchery-reared smolts, released under programmes to mitigate hydropower development schemes; returning fish unable to spawn in the wild and exploited heavily.
7. Improved reporting of rod catches in 1994, and data derived from carcass tagging and logbooks from 2002.
8. Catch on River Foyle allocated 50% Ireland and 50% Northern Ireland.
9. Angling catch (derived from carcass tagging and logbooks) first included in 2002.
10. Data for France include some unreported catches.
11. Spanish data until 2018 (inclusive), weights estimated from mean weight of fish caught in Asturias (80–90% of Spanish catch). Weight for 2019 for all Spain, supplied via data call.
12. Between 1991 and 1999, there was only a research fishery at Faroes. In 1997 and 1999, no fishery was conducted; the commercial fishery resumed in 2000, but has not operated since 2001.
13. Includes catches made in the West Greenland area by Norway, Faroes, Sweden, and Denmark in 1965–1975.
14. Includes catches in Norwegian Sea by vessels from Denmark, Sweden, Germany, Norway, and Finland.
15. No unreported catch estimate available for Canada in 2007 and 2008. Data for Canada in 2009, 2010, and 2019 are incomplete. No unreported catch estimate available for Russia since 2008.
16. Estimates refer to season ending in given year.

Table 6 The catches (tonnes round fresh weight) and % of the nominal catches by country/jurisdiction taken in coastal, estuarine, and in-river fisheries, 2000–2019 (2019 values include provisional data).

Table 7 Estimates of unreported catches by various methods in tonnes by country within national EEZs in the Northeast Atlantic, North American, and West Greenland Commissions of NASCO for 2019.

Commission area	Country	Unreported catch (tonnes)	Unreported as % of total North Atlantic catch (unreported + reported)	Unreported as % of national catch (unreported + reported)
NEAC	Denmark	5	0.4	28
NEAC	Finland	3	0.3	12
NEAC	Iceland	1	0.1	2
NEAC	Ireland	4	0.4	9
NEAC	Norway	220	19.5	30
NEAC	Sweden	2	0.1	9
NEAC	UK (England and Wales)	1	0.1	13
NEAC	UK (Northern Ireland)	0.3	0.0	8
NEAC	UK (Scotland)	1	0.1	9
NAC	USA	0	0.0	0
NAC	Canada	12	1.0	11
WGC	Greenland	10	0.9	25
Total unreported catch*		258	22.9	
Total reported catch of North Atlantic salmon		869		

* No unreported catch estimates are available for France, Spain, St Pierre and Miquelon, or Russia in 2019.

Table 8 Numbers of fish caught and released in rod fisheries along with the % of the total rod catch (released + retained) for countries in the North Atlantic, where records are available, 1991–2019. Values for 2019 are provisional.

Year	Canada (4)		USA		Iceland		Russia (1)		UK (England and Wales)		UK (Scotland)		Ireland		UK (N. Ireland) (2)		Denmark		Sweden		Norway (3)

Key:

1. Since 2009, data are either unavailable or incomplete; however, catch-and-release is considered to have remained at similar high levels as previously.
2. Data for 2006–2009, 2014 is for the Department of Culture, Arts and Leisure area only; the values from 2010 are a total for UK (Northern Ireland). Data for 2015, 2016, and 2017 are for River Bush only.
3. The statistics were collected on a voluntary basis, the numbers reported must be viewed as a minimum.
4. Released fish in the kelt fishery of New Brunswick are not included in the totals for Canada.

Annex 1 Glossary of acronyms and abbreviations

1SW (*one-sea-winter*). Maiden adult salmon that has spent one winter at sea.

2SW (*two-sea-winter*). Maiden adult salmon that has spent two winters at sea.

ACOM (*ICES Advisory Committee*). The Committee works on the basis of scientific assessment prepared in ICES expert groups. The advisory process includes peer review of the assessment before it can be used as the basis for advice. The Advisory Committee has one member from each ICES Member Country under the direction of an independent chair, appointed by the Council.

CL, i.e. S_{lim} (*conservation limit*). Demarcation of undesirable stock levels or levels of fishing activity; the ultimate objective of fisheries management will be to ensure a high probability of undesirable levels being avoided.

C&R (*catch-and-release*). Catch-and-release is a practice within recreational fishing intended as a technique of conservation. After capture, the fish are unhooked and returned to the water before experiencing serious exhaustion or injury. Using barbless hooks, it is often possible to release the fish without removing it from the water (a slack line is frequently sufficient).

CWT (*coded wire tag*). The CWT is a length of magnetized stainless steel wire, 0.25 mm in diameter. The tag is marked with rows of numbers, denoting specific batch or individual codes. Tags are cut from rolls of wire by an injector that hypodermically implants them into suitable tissue. The standard length of a tag is 1.1 mm.

DNA (*deoxyribonucleic acid*). DNA is a nucleic acid that contains the genetic instructions used in the development and functioning of all known living organisms (with the exception of RNA – Ribonucleic Acid viruses). The main role of DNA molecules is the long-term storage of information. DNA is often compared to a set of blueprints, like a recipe or a code, since it contains the instructions needed to construct other components of cells, such as proteins and RNA molecules.

DST *(data storage tag*). A miniature data logger that is attached to fish and other marine animals, measuring salinity, temperature, and depth.

EEZ *(Exclusive Economic Zone*). EEZ is a concept adopted at the Third United Nations Conference on the Law of the Sea, whereby a coastal state assumes jurisdiction over the exploration and exploitation of marine resources in its adjacent section of the continental shelf, taken to be a band extending 200 miles from the shore.

ICES (*International Council for the Exploration of the Sea*). A global organization that develops science and advice to support the sustainable use of the oceans through the coordination of oceanic and coastal monitoring and research, and advising international commissions and governments on marine policy and management issues.

MSY (*maximum sustainable yield*). The largest average annual catch that may be taken from a stock continuously without affecting the catch of future years. A constant long-term MSY is not a reality in most fisheries, where stock sizes vary with the strength of year classes moving through the fishery.

MSW (*multi-sea-winter*). A MSW salmon is an adult salmon that has spent two or more winters at sea and may be a repeat spawner.

NAC (*North American Commission*). The North American Atlantic Commission of NASCO or the North American Commission area of NASCO.

NASCO (*North Atlantic Salmon Conservation Organization*). An international organization, established by an inter-governmental convention in 1984. The objective of NASCO is to conserve, restore, enhance, and rationally manage the fisheries of Atlantic salmon through international cooperation, taking account of the best available scientific information.

NEAC (*North-East Atlantic Commission*). The North-East Atlantic Commission of NASCO or the North-East Atlantic Commission area of NASCO.

NEAC–N (*North-East Atlantic Commission – northern area*). The northern portion of the North-East Atlantic Commission area of NASCO.

NEAC–S (*North-East Atlantic Commission – southern area*). The southern portion of the North-East Atlantic Commission area of NASCO.

PFA (*pre-fishery abundance*). The numbers of salmon estimated to be alive in the ocean from a particular stock at a specified time. In the previous version of the stock complex Bayesian PFA forecast model, two productivity parameters are calculated, for the *maturing* (PFAm) and *non-maturing* (PFAnm) components of the PFA. In the updated version only one productivity parameter is calculated; this parameter is used to calculate total PFA, which is then split into PFAm and PFAnm based upon the *proportion of PFAm* (p.PFAm).

PIT (*passive integrated transponder*). PIT tags use radio frequency identification technology. PIT tags lack an internal power source. They are energized on encountering an electromagnetic field emitted from a transceiver. The tag's unique identity code is programmed into the microchip's nonvolatile memory.

SER (*spawning escapement reserve*). The CL increased to take account of natural mortality between the recruitment date (assumed to be the 1st of January) and the date of return to home waters.

S_{lim}, i.e. CL (*conservation limit*). Demarcation of undesirable stock levels or levels of fishing activity; the ultimate objective when managing fisheries of these stocks will be to ensure that there is a high probability that the undesirable levels are avoided.

S_{MSY} (*spawners for maximum sustainable yield*). The spawner abundance that generates recruitment at a level that provides a maximum exploitable yield (recruitment minus spawners).

VIE (Visible Implant Elastomer). VIE is injected into fish to identify individuals by colour or tag position.

WGC (*West Greenland Commission*). The West Greenland Commission of NASCO or the West Greenland Commission area of NASCO.

WGNAS (*Working Group on North Atlantic Salmon*). ICES working group responsible for the annual assessment of the status of salmon stocks across the North Atlantic and formulating catch advice for NASCO.

Atlantic salmon from the Northeast Atlantic

Summary of advice for fishing season 2020/2021

ICES advises that when the Framework of Indicators (FWI) was applied in early 2020, a full reassessment was not required and the 2018 ICES advice remains valid: "when the MSY approach is applied there are no mixed-stock fisheries options on the NEAC complexes at the Faroes for the fishing seasons 2018/2019 to 2020/2021". 2020 marks the final year of NASCO's three year decision regarding the salmon fishery in the Faroese Waters (NASCO, 2018).

The FWI previously developed in support of the multiyear catch advice was revised in 2018. ICES recommended that, since the zero catch options at Faroes are the result of the current status of both Southern NEAC stock complexes (i.e. maturing and non-maturing sea age groups) and the Northern NEAC maturing stock complex, the FWI applied in January 2019 and 2020 should be based only on these three stock complexes (ICES, 2018). NASCO agreed that this revised FWI would be used in these years.

ICES advises that when the MSY approach is applied, fishing should only take place on salmon from rivers where stocks have been shown to be at full reproductive capacity. Mixed-stock fisheries present particular threats, and should be managed based on the individual status of all stocks exploited in the fishery.

NASCO 2.1NASCO has asked ICES to describe the key events of the 2019 fisheries

No significant changes in gear type used were reported in the NEAC area in 2019.

No fishery for salmon has been prosecuted at the Faroes after 2000.

New regulatory provisions approved for UK (England) in December 2018 substantially reduced the exploitation of salmon in 2019. The measures included the closure of most net fisheries, including all driftnet fisheries and mandatory release of salmon caught in net fisheries authorized to operate for sea trout.

The reported nominal catch in the NEAC area in 2019 is 743 t, with 77 t reported in the Southern NEAC and 666 t in the Northern NEAC areas. Estimates of unreported catches in the NEAC area were 237 t in total. As in previous years, the location of catches differed between Southern NEAC and Northern NEAC (Table 1). In 2019, in-river fisheries accounted for 68% of the catches in Southern NEAC, 32% came from estuarine fisheries, and 0% from coastal fisheries. In Northern NEAC, on the other hand, coastal fisheries accounted for 36% of the catches, with the remaining 64% of the catches coming from in-river fisheries.

Table 1 Salmon catches (in tonnes) and location of catches in the NEAC areas in 2019.

Salmon catches	Southern NEAC	Northern NEAC	Faroes	Total NEAC
2019 nominal catch (tonnes)	77	666	0	743
Catch as per cent of NEAC total	10	90	0	100
Unreported catch (tonnes)	6	231	-	237
Location of catches	Southern NEAC	Northern NEAC	Faroes	Total NEAC
% in-river	68	64	-	64
% in estuaries	32	0	-	3
% coastal	0	36	-	33

The NEAC area has seen a general reduction in catches since the 1980s (Figure 1, Table 2). This reflects the decline in fishing effort as a consequence of management measures, as well as a reduction in the size of stocks. The nominal catch for 2019 (743 t) was below that in 2018 (927 t), and the lowest in the time-series in both areas. The catch in Southern NEAC, which constituted around two-thirds of the total NEAC catch in the early 1970s, has been lower than that of Northern NEAC since 1999 (Figure 1).

1SW salmon constituted 44% of the total catch in Northern NEAC in 2019 (Figure 2). For the Southern NEAC countries, the overall percentage of 1SW fish in the catch in 2019 was estimated at 63%.

The contribution of escaped farmed salmon to national catches in the NEAC area in 2019 was generally low in most countries, and similar to the values that have been reported in previous years. Estimates of farmed fish in Norwegian angling catches were in the lower range of observed values in the time-series (3%), while the proportion estimated in Norwegian river populations in the autumn showed an increase on the previous year (7%). No current data are available for the proportion of farmed salmon in coastal fisheries. Small numbers of escaped farmed salmon were also reported from catches in Icelandic and Scottish rivers (6 and 20 fish, respectively) in 2019.

Estimated exploitation rates have decreased since the early 1980s in both the Northern and Southern NEAC areas (Figure 3). The exploitation rates on 1SW and MSW salmon have become similar, with higher exploitation rates in Northern NEAC at around 40% compared to 10% in Southern NEAC.

Estimates of the number of salmon caught and released in angling fisheries are not complete for all NEAC countries. There are large differences between countries in the percentage of the total angling catch that is released: in 2019 this ranged from 20% in Sweden to 92% in UK (Scotland), reflecting varying management practices and angler attitudes among these countries. Catch and release mortality estimates are also available for some countries, but these are not included in the nominal catch.

[1] All Icelandic catches have been included in Northern NEAC.

[2] Since 1991, fishing carried out at the Faroes has only been for research purposes.

[3] No unreported catch estimate available for Russia since 2008.

[4] Estimates refer to season ending in the given year.

NASCO 2.2 NASCO has asked ICES to review and report on the development of age-specific stock conservation limits

River-specific conservation limits (CLs) (in terms of either egg or spawner requirements) for both 1SW and MSW salmon have been estimated for stocks in most countries/jurisdictions in the NEAC area (France, Ireland, UK (England and Wales), UK (Northern Ireland), Finland, Norway, and Sweden). Preliminary results are also available for a small number of rivers in Russia. Where sufficient numbers of CL estimates are available for individual rivers, these are summed to provide estimates at a country/jurisdiction level. For countries/jurisdictions that have not applied this approach (Russia, UK (Scotland), and Iceland), an interim approach was used to estimate national CLs. This approach is based on the establishment of pseudo stock–recruitment relationships for salmon stocks that are updated annually; as a result the CLs may change slightly year to year.

In UK (Scotland), further progress has been made in establishing CLs at the scale of the river stock, or on groups of smaller neighbouring rivers where angling data are not yet available by river. A new approach to defining river-specific CLs has been developed using a Bayesian hierarchical modelling framework. This was used to define CLs for 11 Scottish rivers with stock and recruitment data. By pooling information from multiple rivers and incorporating information about local environmental covariates, CL estimates have also been transferred to other rivers without such data, to a total number of 173 areas assessed annually. Investigations are continuing to determine whether alternative stock–recruitment relationships and additional river covariates can improve the current model.

In Iceland, during 2018–2019, CLs were set for 12 rivers, mostly in West Iceland. All of these are important salmon fisheries that contribute around 33% of the total annual rod catch of wild salmon.

To provide catch advice to NASCO, CLs are required for stock complexes. These were derived either by summing individual river CLs to country/jurisdiction level, or by taking overall CLs as provided by the model, and then summing to the level of the four NEAC stock complexes. Spawner escapement reserves (SERs) are CLs (expressed in terms of spawner numbers), adjusted to take account of natural mortality (M = 0.03 per month) between 1 January of the first winter at sea and return time to homewaters for each of the maturing (6–9 months) and non-maturing (16–21 months) 1SW salmon components from the Northern NEAC and Southern NEAC stock complexes.

National stocks within the NEAC area are combined into two geographic groups for the provision of management advice for the distant-water fisheries at West Greenland and the Faroes. The Northern group consists of Russia, Finland, Norway, Sweden, and the northeastern region of Iceland. The Southern group consists of UK (Scotland), UK (England and Wales), UK (Northern Ireland), Ireland, France, and the southwestern region of Iceland.

CLs and SERs are provided for the four stock complexes, defined as two sea ages per geographic group (Table 3), by summing country/jurisdiction CLs to the level of the four NEAC stock complexes.

Table 3 Conservation limits (CL) and spawner escapement reserves (SER) for the four salmon stock complexes (combination of regional group and sea age) in the NEAC area in 2019.

Regional group	Age group	CL (number)	SER (number)
Northern NEAC	1SW	133 245	168 843
	MSW	119 687	204 939
Southern NEAC	1SW	593 735	754 678
	MSW	295 781	502 353

For the nine countries/jurisdictions where river-specific CLs are available, time-series indicating the development in the definition of river-specific CLs, the number of rivers annually assessed against CLs, and the number of rivers that annually meet or exceed CLs (based on spawner numbers, after fisheries) are provided in Figure 4. This figure illustrates the increase in the number of CLs established within individual countries/jurisdictions. Iceland has (since 2018–2019) thirteen rivers with established CLs, of which one river has been assessed annually since 2000. Ten of the 17-year time-series have been below the CL, and four out of the past five years have been above the CL. The time-series for the river in Iceland assessed since 2000 is not included in Figure 4 or Table 4.

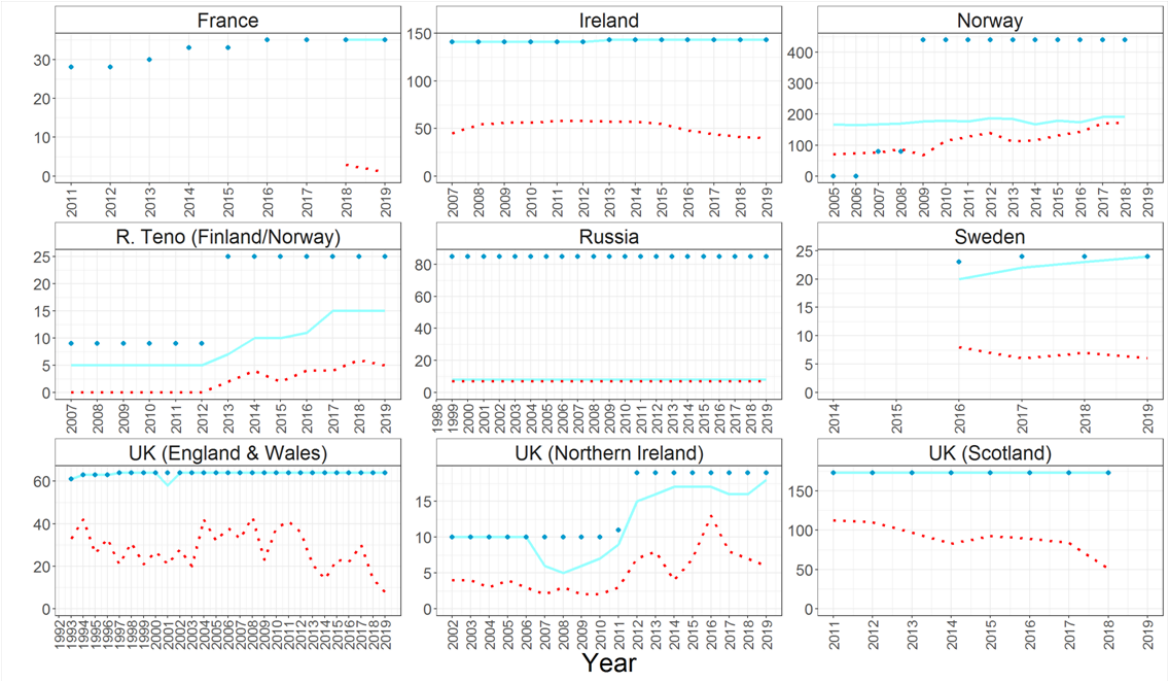

Figure 4 Time-series of countries/jurisdictions in the NEAC area to 2019 (2018 for Norway and UK Scotland), showing the number of rivers with established CLs and trends in the number of stocks meeting CLs (•–•–• number of rivers with established CLs; — number of rivers assessed for attainment of CLs; . . . . . number of rivers meeting or exceeding CLs). Note: data for France prior to 2018 are currently under review.

NASCO 2.3 NASCO has asked ICES to describe the status of the stocks

Recruitment, expressed as pre-fishery abundance (PFA; split by maturing and non-maturing 1SW salmon, at 1 January of the first winter at sea) is estimated by geographic groups (Northern NEAC and Southern NEAC), and individual country/jurisdiction, and assessed relative to the spawner escapement reserve (SER).

The assessment of PFA against SER for the four complexes over the time-series is shown in Figure 5, and by country/jurisdiction for the most recent year in Figure 6. The time-series of returns and spawners against CLs are shown by sea age groups for the Northern NEAC and Southern NEAC complexes (Figure 5), and for 2019 by individual countries/jurisdictions for 1SW maturing and MSW (1SW non-maturing at the PFA stage) salmon (Figure 6). These assessments show the same broad contrasts between Northern and Southern NEAC stocks seen in the stock complex data.

PFA relative to SER

For Northern NEAC PFAs of both maturing 1SW and non-maturing 1SW salmon show a general decline over the time period (since 1983), with the decline being more marked in the maturing 1SW stock (Tables 5 and 6, Figure 5). Both stock complexes have, however, been at full reproductive capacity prior to the distant-water fisheries (i.e. meeting the SER with at least 95% probability) throughout the time-series. In the most recent year, both maturing and non-maturing 1SW salmon in all Northern NEAC countries were at full reproductive capacity with the exception of Finland/Norway (River Teno/Tana), Iceland, and Russia where maturing 1SW salmon were at risk of suffering or suffering reduced reproductive capacity (Figure 6).

For Southern NEAC PFAs of maturing 1SW and of non-maturing 1SW salmon (Tables 5 and 6, Figure 5) demonstrate broadly similar declining trends over the time period (since 1971). Both stock complexes were at full reproductive capacity prior to distant-water fisheries throughout the early part of the time-series. However, in most years since the early 1990s, the non-maturing 1SW stock has either been at risk of suffering or suffering reduced reproductive capacity before any fisheries took place. The maturing 1SW stock, on the other hand, was first assessed as being at risk of suffering reduced reproductive capacity in 2009, and has been either at risk of suffering or suffering reduced reproductive capacity in the majority of the years since then. With the exception of UK (Northern Ireland), the maturing 1SW salmon in all Southern NEAC

countries/jurisdictions in the most recent year were suffering reduced reproductive capacity (Figure 6); UK (Northern Ireland) was at full reproductive capacity. For the non-maturing 1SW salmon, stocks are either at risk of suffering or suffering reduced reproductive capacity prior to distant-water fisheries in most countries, except UK (England and Wales) and France where stocks are assessed to be at full reproductive capacity (Figure 6).

Spawners relative to CLs

In the Northern NEAC stock complex 1SW spawners have been at full reproductive capacity (i.e. meeting the CL with at least 95% probability) throughout the time-series. However, spawners have been at reduced levels since 2007 (Figure 5). MSW spawners have been at full reproductive capacity since 2006. Both 1SW and MSW stock complexes were at full reproductive capacity in 2019, although 1SW spawners were among the lowest in the time-series. In Northern NEAC countries, 1SW spawners in 2019 were at full reproductive capacity in Sweden and Norway, but at risk of suffering reduced reproductive capacity in Russia, and suffering reduced reproductive capacity in Iceland and Finland/Norway (River Teno/Tana) (Figure 7). MSW spawners in 2019 were at full reproductive capacity in Norway and Sweden, at risk of suffering reduced reproductive capacity in Iceland and Russia, and suffering reduced reproductive capacity in Finland/Norway (River Teno/Tana) (Figure 8).

For the Southern NEAC, there has been a progressive decline in 1SW spawner numbers (Figure 5). This sea age group has been either at risk of suffering or suffering reduced reproductive capacity for most of the time-series, and has been suffering reduced reproductive capacity consistently over the last six years. MSW spawners in Southern NEAC declined up to the late 1990s but have increased since this time. However, this sea age group has been either at risk of suffering or suffering reduced reproductive capacity in most years throughout the time-series. In 2019, Southern NEAC MSW spawners were suffering reduced reproductive capacity. In Southern NEAC countries/jurisdictions, 1SW spawners in 2019 were suffering reduced reproductive capacity, except for stocks in UK (Northern Ireland) that were at full reproductive capacity (Figure 7). MSW spawners in 2019 were either at risk of suffering or suffering reduced reproductive capacity, except for stocks in UK (England and Wales) that were at full reproductive capacity (Figure 8).

Trends in rivers meeting CLs

In the NEAC area, nine jurisdictions currently assess salmon stocks using river-specific CLs (Figure 4 and Table 4). The attainment of CLs is assessed based on spawners, after fisheries.

Table 4 Summary of the attainment of CLs in 2019 (2018 for Norway and UK [Scotland]) and trends based on all available data in the NEAC area. Further details can be found in ICES (2020).

Country /Jurisdiction	Number of rivers with CLs	Number of rivers assessed for compliance	Number of rivers attaining CL	% of assessed rivers attaining CL	Trend statement
Northern NEAC					
Russia	85	8	7	88	No trend
Finland/Norway (Teno/Tana)	25	15	5	33	Stable
Norway	439	193	171	89	Increasing
Sweden	24	24	6	25	Stable (data for 2016 to 2019 only)
Iceland	13	1	1	100	Not applicable as only one river assessed
Southern NEAC					
UK (Scotland)	173	173	51	29	Decreasing
UK (Northern Ireland)	19	18	6	33	Decreasing
UK (England and Wales)	64	64	8	13	Decreasing
Ireland	143	143	40	28	Decreasing
France	35	35	1	3	No trend (2018 and 2019 data only)

Marine survival

Return rate estimates, a proxy for marine survival, are derived for a limited number of rivers, of different time-series duration. Despite management measures aimed at reducing exploitation in recent years, there has been an overall

declining trend since 1980 in the return rates of 1SW wild and hatchery-origin smolts in both Northern and Southern NEAC areas, indicating poor survival of 1SW salmon in the marine environment (Figure 9).

A declining trend is not evident for the 2SW wild components in either area (no data are available for hatchery-origin 2SW return rates for Southern NEAC and no estimates are provided for other MSW categories).

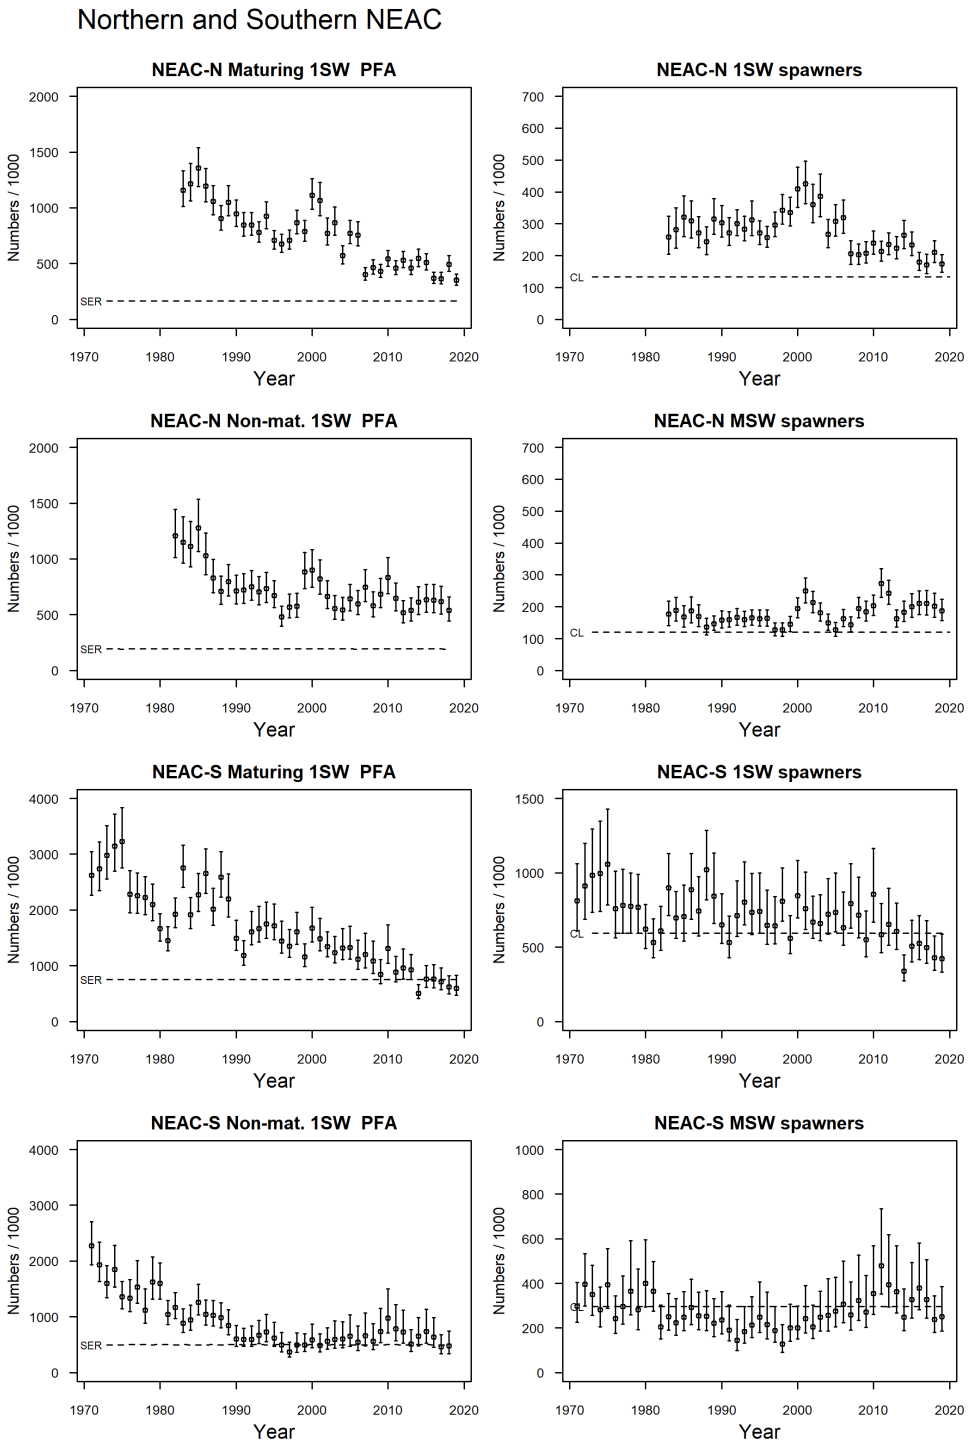

Figure 5 Pre-fishery abundance (PFA – recruits; left panels) and spawners (right panels), with 90% confidence limits, for maturing 1SW (spawning as 1SW) and non-maturing 1SW (spawning as MSW) salmon in Northern NEAC (NEAC-N) and Southern NEAC (NEAC-S). The dashed horizontal lines in the left panels are the respective 2019 spawning escapement reserve (SER) values, and in the right panels the conservation limit (CL) values.

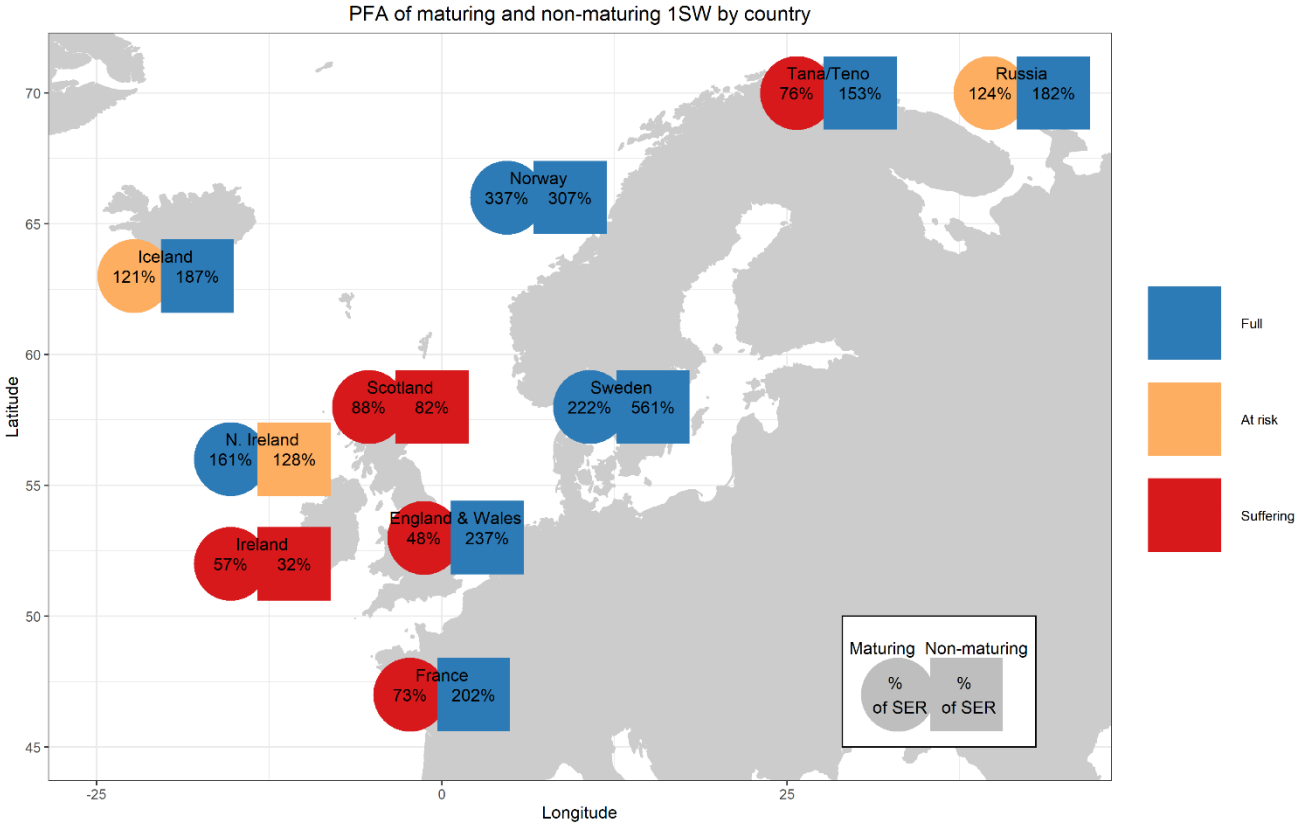

Figure 6 PFA of maturing (for 2019) and non-maturing (for 2018) as percentage of the respective spawner escapement reserve (% of SER). The percentage of SER is based on the median of the Monte Carlo distribution. The colour shading represents the three stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the SER); At risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the SER, but the 5th percentile is below); and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the SER).

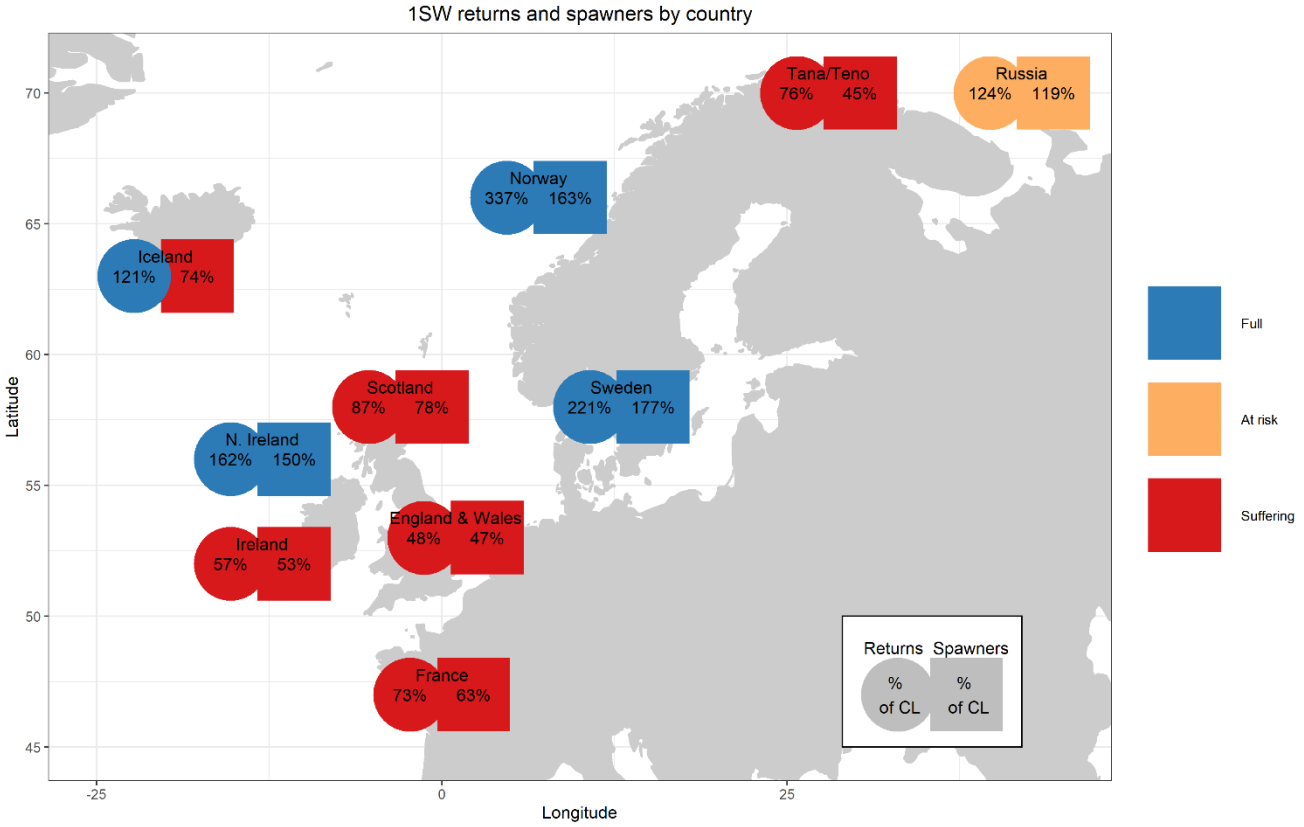

Figure 7 1SW returns and spawners as percentage of respective conservation limit (% of CL) for 2019. The percentage of CL is based on the median of the Monte Carlo distribution. The colour shading represents the three stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the CL); At risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the CL, but the 5th percentile is below); and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the CL).

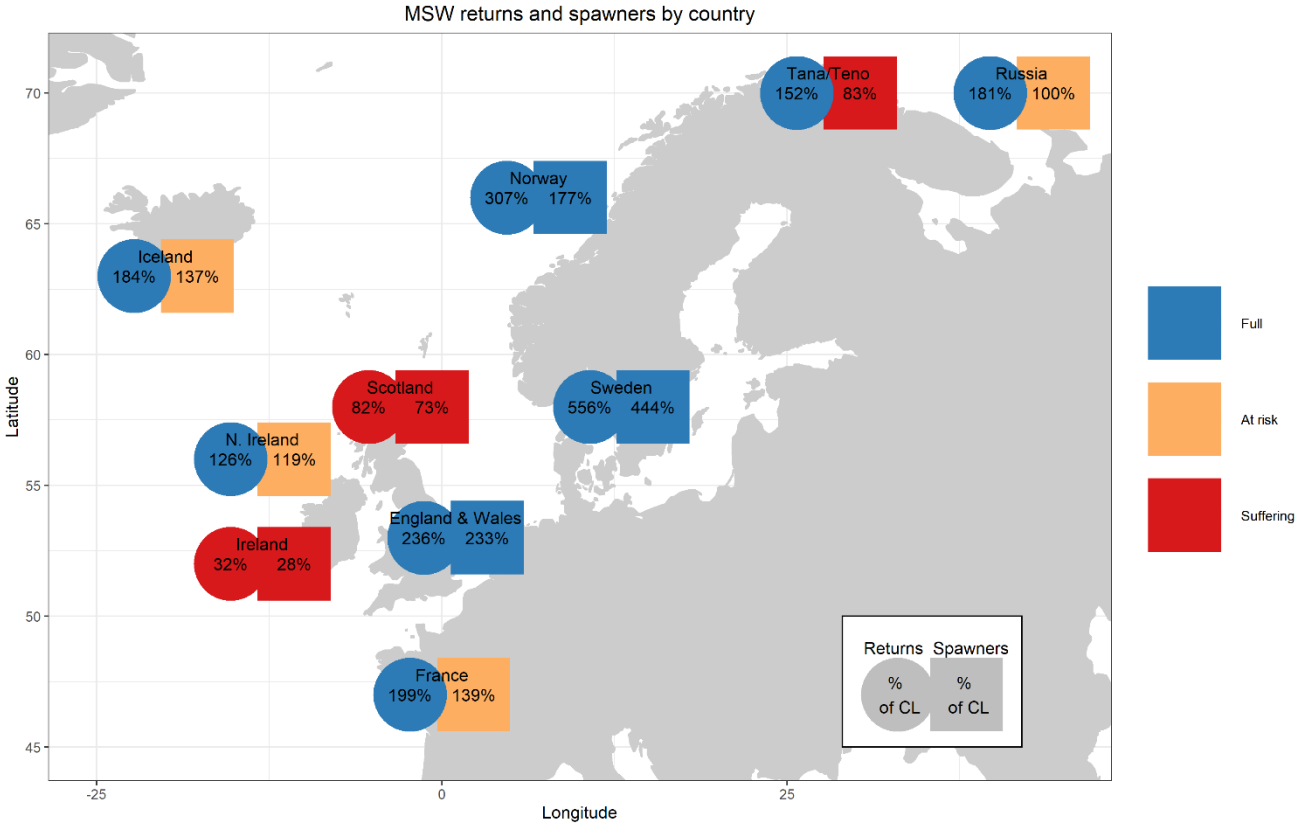

Figure 8 MSW returns and spawners as percentage of respective conservation limit (% of CL) for 2019. The percentage of CL is based on the median of the Monte Carlo distribution. The colour shading represents the three stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the CL); At risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the CL, but the 5th percentile is below); and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the CL).

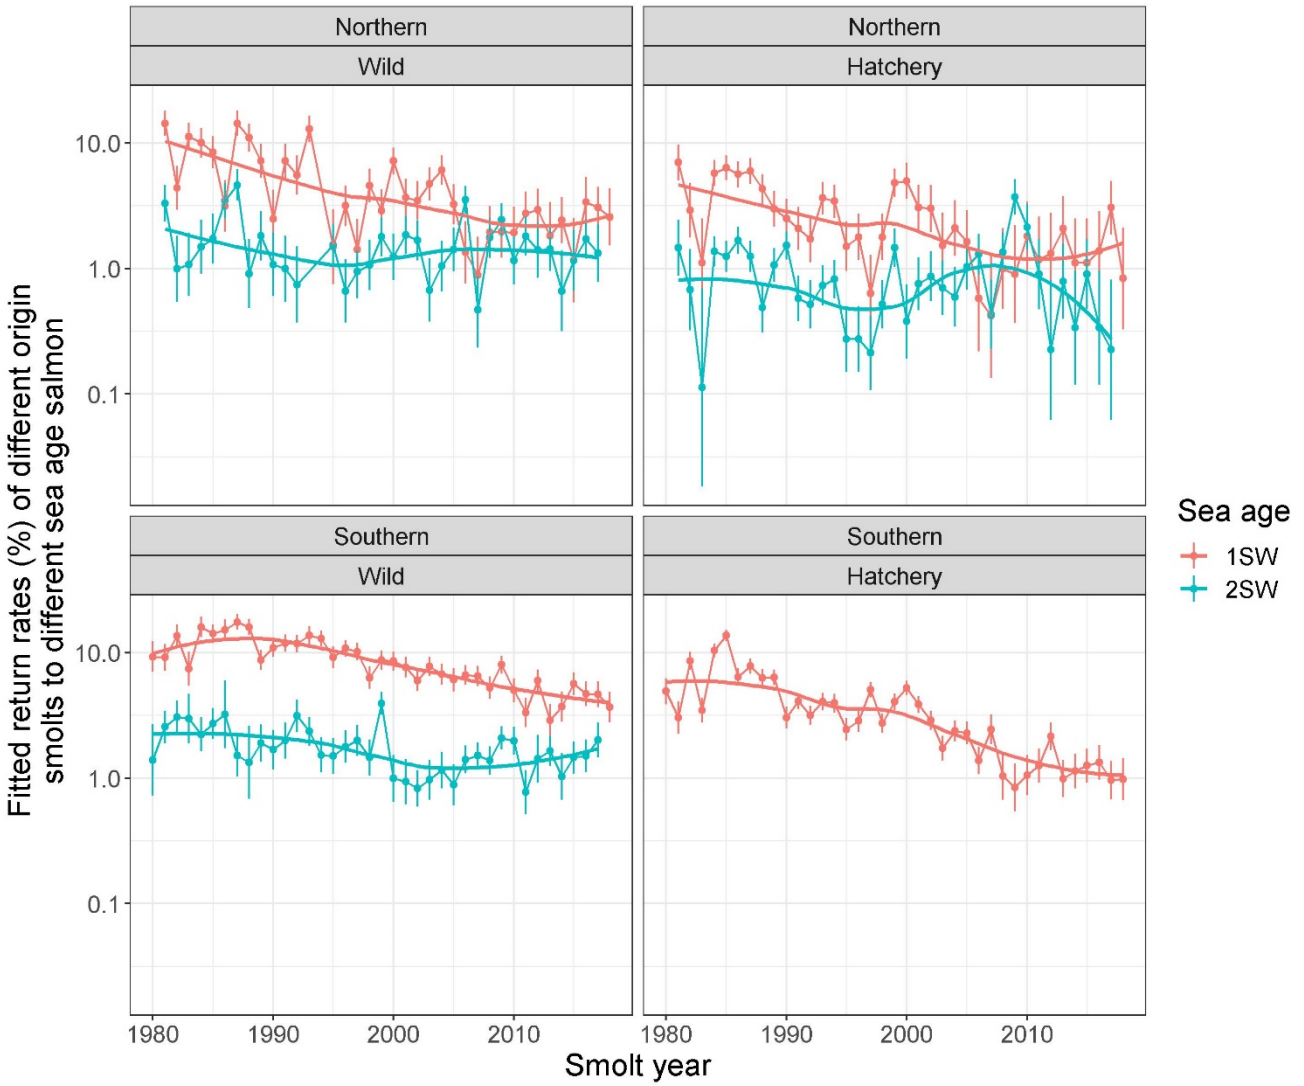

Figure 9 Return rates: Annual least squared (marginal mean) estimates of return rates (%) of wild (left-hand panels) and hatchery origin smolts (right-hand panels) to 1SW (red) and 2SW (blue) salmon to Northern (top panels) and Southern NEAC areas (bottom panels). For most rivers in Southern NEAC, the values are returns to the coast prior to the homewater coastal fisheries. Annual means derived from a general linear model analysis of rivers in a region with a quasi-Poisson distribution (log-link function). Error bars are standard errors. Note the *y*-axis is on a log scale.

Table 5 Estimated pre-fishery abundance (by number, median values) of maturing 1SW salmon (potential 1SW returns) by NEAC country/jurisdiction and year. Bold values represent the median estimate of pre-fishery abundance (PFA) by year.

Annex 1 Glossary of acronyms and abbreviations

1SW *(one-sea-winter).* Maiden adult salmon that has spent one winter at sea.

2SW (*two-sea-winter*). Maiden adult salmon that has spent two winters at sea.

CL (or **CLs**)**, i.e. S_{lim}** *(conservation limit).* Demarcation of undesirable stock levels or levels of fishing activity; the ultimate objective when managing stocks and regulating fisheries will be to ensure that there is a high probability that undesirable levels are avoided.

FWI *(Framework of Indicators).* The FWI is a tool used to indicate if any significant change in the status of stocks used to inform the previously provided multi-annual management advice has occurred.

ICES (*International Council for the Exploration of the Sea*).

MSY (*maximum sustainable yield*). The largest average annual catch that may be taken from a stock continuously without affecting the catch of future years; a constant long-term MSY is not a reality in most fisheries, where stock sizes vary with the strength of year classes moving through the fishery.

MSW (*multi-sea-winter*). A MSW salmon is an adult salmon which has spent two or more winters at sea and may be a repeat spawner.

NASCO (*North Atlantic Salmon Conservation Organization*). An international organization, established by an inter-governmental convention in 1984. The objective of NASCO is to conserve, restore, enhance, and rationally manage Atlantic salmon through international cooperation, taking account of the best available scientific information.

NEAC (*North East Atlantic Commission).* The commission within NASCO with responsibility for Atlantic salmon in the Northeast Atlantic.

PFA *(pre-fishery abundance).* The numbers of salmon estimated to be alive in the ocean from a particular stock at a specified time.

SER *(spawning escapement reserve).* The CL increased to take account of natural mortality between the recruitment date (assumed to be 1st January) and the date of return to homewaters.

Annex 2* General considerations

Management plans

The North Atlantic Salmon Conservation Organization (NASCO) has adopted an Action Plan for Application of the Precautionary Approach which stipulates that management measures should be aimed at maintaining all stocks above their conservation limits (CLs) by the use of management targets. CLs for North Atlantic salmon stock complexes have been defined by ICES as the level of a stock (number of spawners) that will achieve long-term average maximum sustainable yield (MSY). NASCO has adopted the region-specific CLs as limit reference points (S_{lim}); having populations fall below these limits should be avoided with high probability. Advice for the Faroes fishery (which historically harvested both 1SW and MSW salmon) is currently based upon all NEAC area stocks. The advice for the West Greenland fishery (ICES, 2018a) is based upon the Southern NEAC non-maturing 1SW stock and the non-maturing 1SW salmon from North America. A 75% risk level (probability) of achieving the management objectives simultaneously in the six North American regions and Southern NEAC has been agreed by NASCO for the provision of catch advice at West Greenland. No specific risk level has so far been agreed by NASCO for the provision of catch advice for the Faroes fishery; in the absence of this, ICES uses a 95% probability of meeting individual conservation limits, which can be applied at the level of the European stock complexes (two areas and two age classes) and the NEAC countries (ten countries and two age classes). A framework of indicators has been developed in support of the multi-annual catch options.

Biology

Atlantic salmon (*Salmo salar*) is an anadromous species found in rivers of countries bordering the North Atlantic. In the Northeast Atlantic area, their current distribution extends from northern Portugal to the Pechora River in Northwest Russia and Iceland. Juveniles emigrate to the ocean at ages of one to eight years (dependent on latitude) and generally return after one or two years at sea. Long-distance migrations to ocean feeding grounds are known to take place, with adult salmon from the Northeast Atlantic stocks being exploited at both West Greenland and the Faroes.

Environmental influence on the stock

Environmental conditions in both freshwater and marine environments have a marked effect on the status of salmon stocks. Across the North Atlantic, a range of problems in the freshwater environment play a significant role in explaining the poor status of stocks. In many cases, river damming and habitat deterioration have had a devastating effect on freshwater environmental conditions. In the marine environment, return rates of adult salmon have declined through the 1980s and, for some stocks, are now at their lowest levels in the time-series, even after closure of marine fisheries. Climatic factors modifying ecosystem conditions and the impact of predators of salmon at sea are considered to be the main contributing factors of lower productivity, which is expressed almost entirely in terms of lower marine survival.

Effects of the fisheries on the ecosystem

Salmon fisheries have no, or only minor, influence on the marine ecosystem. The exploitation of salmon in freshwater may affect the riverine ecosystem through changes in species composition. There is limited knowledge of the magnitude of these effects.

Quality considerations

Uncertainties in input variables to the stock status and stock forecast models are incorporated in the assessment.

* Version 2: All text prior to the Scientific basis table inserted

Scientific basis

ICES stock data category	1 (ICES, 2019a).
Assessment type	Run–reconstruction models and Bayesian forecasts, taking into account uncertainties in data and process error. Results presented in a risk analysis framework.
Input data	Nominal catches (by sea-age class) for commercial and recreational fisheries. Estimates of unreported/illegal catches. Estimates of exploitation rates. Natural mortalities (from earlier assessments).
Discards and bycatch	Discard data are included in risk-based framework for the Faroes fishery. Not relevant for other NEAC assessments.
Indicators	Framework of Indicators (FWI) is used to indicate if a significant change has occurred in the status of stocks in intermediate years where multi-annual management advice applies.
Other information	Advice subject to annual review. Stock annex developed in 2014 and updated in 2019 (ICES, 2019b).
Working group	Working Group on North Atlantic Salmon (WGNAS) (ICES, 2020).

Atlantic salmon from North America

Summary of the advice for 2020

ICES advises that when the Framework of Indicators (FWI) was applied in early 2020, a full reassessment was not required and the 2018 ICES advice remains valid. Consequently, in line with the management objectives agreed by the North Atlantic Salmon Conservation Organization (NASCO) and consistent with the MSY approach, there are no mixed-stock fishery options on 1SW non-maturing and 2SW salmon components from North American stocks in 2020. 2020 marks the final year of NASCO's three year multi-annual regulatory measure for fishing Atlantic salmon at West Greenland (NASCO, 2018).

ICES advises that when the MSY approach is applied, fishing should only take place on salmon from rivers where stocks are at full reproductive capacity. Mixed-stock fisheries present particular threats, and should be managed based on the individual status of all stocks exploited in the fishery.

NASCO 3.1 Describe the key events of the 2019 fisheries (including the fishery at Saint Pierre and Miquelon)

The provisional catch of Atlantic salmon in eastern North America in 2019 was estimated at 95.1 tonnes (t), of which 93.8 t was reported from Canada, 1.3 t from France (Islands of Saint Pierre and Miquelon, located off the southern coast of Newfoundland), and 0 t from USA (Tables 1 and 2; Figure 1). There were no commercial or recreational fisheries for Atlantic salmon in USA in 2019. The dramatic decline in harvested tonnage since 1980 is in large part the result of the reductions in commercial fisheries effort, with the closure of the Newfoundland commercial fishery in 1992, the Labrador commercial fishery in 1998, and the Québec commercial fishery in 2000. All commercial fisheries for Atlantic salmon remained closed in Canada in 2019.

Unreported catch in 2019 was estimated at 11.6 t for Canada and 0 t for USA. France (Islands of Saint Pierre and Miquelon) did not provide an unreported catch value.

The assessment regions for North America are shown in Figure 2.

Three groups exploited salmon in Canada in 2019: indigenous people, residents fishing for food in Labrador, and recreational fishers. No rivers in the Gulf of St Lawrence (henceforth called "Gulf") and Scotia–Fundy regions were opened for retention in recreational fisheries. Mandatory catch-and-release measures were in effect during the period 2015–2019 in the recreational fisheries for the Gulf region. Fishing regulations in Québec limited the retention of small (< 63 cm, fork length) and large salmon (≥ 63 cm – MSW and repeat spawners) to 16 of 114 rivers, and the retention of small salmon only to 56 rivers. Nine rivers were opened to catch-and-release only, and 33 rivers were closed to salmon fishing. Retention of small salmon was only allowed in rivers which were open for recreational fisheries in Newfoundland and Labrador.

For Canada in 2019, 7% of the harvests were taken in coastal areas, entirely from Labrador. The harvest from France (Islands of Saint Pierre and Miquelon) was entirely from coastal areas. Overall for eastern North America in 2019, 40% of the harvests were in-river, 52% from estuaries, and 8% from coastal areas.

Exploitation rates of both large salmon and small salmon (mostly 1SW) remained relatively stable until 1984 and 1992, then declined sharply with the introduction of restrictive management measures (Figure 3). Declines continued in the 1990s. In the last few years, exploitation rates have remained among the lowest in the time-series.

Total recreational catch for Canada in 2019 was 66 575 salmon (45 293 small and 21 282 large salmon), 70% of which were released (26 237 small and 20 098 large salmon).

Table 1 Salmon catches and catch locations in the NAC area in 2019. Catches of NAC-origin salmon at Greenland are reported in the West Greenland Commission area (in tonnes, t).

	Canada					St Pierre & Miquelon	USA	North America

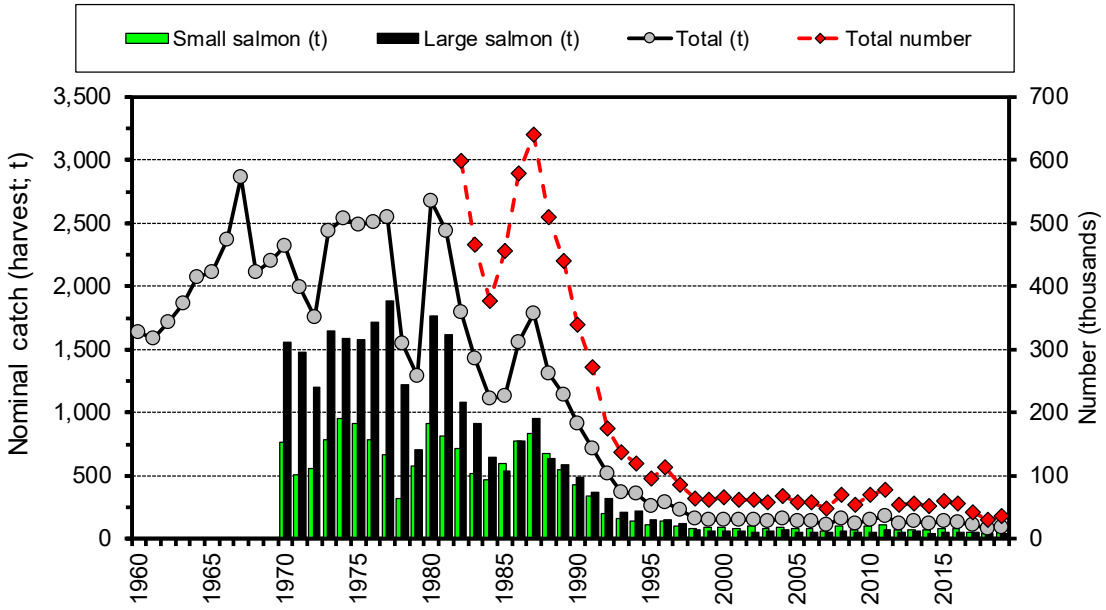

Figure 1 Nominal catch (harvest; t) of small (< 63 cm) and large salmon in Canada (combined harvests in USA and Saint Pierre and Miquelon are ≤ 6 t in any year), from 1960 to 2019.

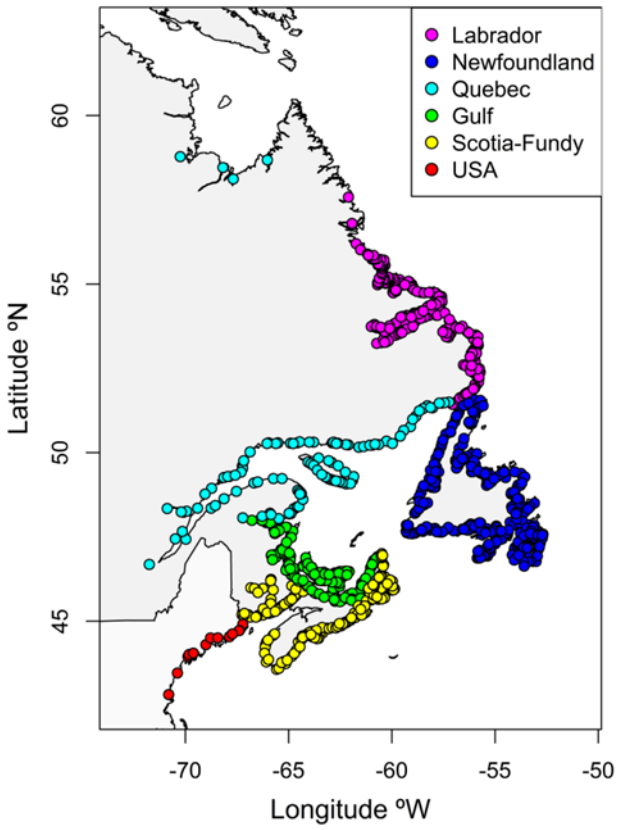

Figure 2 Assessment regions for salmon in the North American Commission area. Dots indicate locations of salmon rivers.

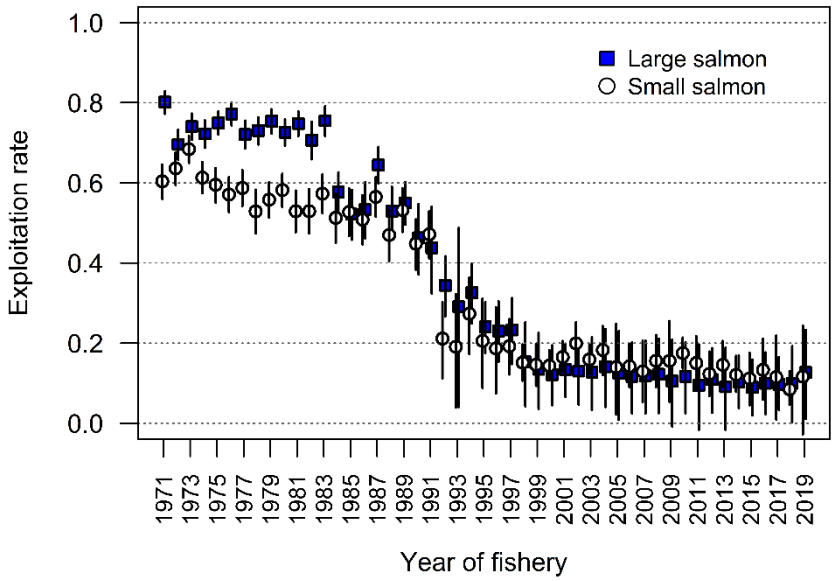

Figure 3 Exploitation rates in North America on small (1SW) (< 63 cm) and large (MSW and repeat spawners) salmon, from 1971 to 2019.

Origin and composition of catches

In the past, salmon from both Canada and the USA were taken in the commercial fisheries of eastern Canada. Sampling programmes of current marine fisheries (Labrador subsistence and Saint Pierre and Miquelon [SPM]) are used to monitor the stock composition of these mixed-stock fisheries.

The stock composition of Atlantic salmon in the Labrador subsistence and SPM mixed-stock fisheries was determined using a single nucleotide polymorphism (SNP) panel range-wide baseline that allows accurate individual assignment to one of 21 North American or ten European reporting groups (Jeffery *et al.*, 2018; ICES, 2019a) (Figure 4). The accuracy of assignment accounting for bias in the SNP analyses was 90%. The reporting groups from the genetic assignments do not correspond directly to the regions used by ICES to characterize stock status and to provide catch advice. Assessment of stock status and provision of catch advice is not possible at the scale of the genetic groups, because historical catch reporting is available at a jurisdictional scale that is broader than the genetic reporting groups. However, the genetic reporting groups can be aligned to the assessment regions (Figure 4).

Assessment region	Genetic Reporting group	Group acronym
Quebec (North) Labrador	Ungava	UNG
	Labrador Central	LAC
	Lake Melville	MEL
	Labrador South	LAS
Quebec	St Lawrence North Shore Lower	QLS

	Northern Norway	NNO
	Iceland	ICE
	Greenland	GL

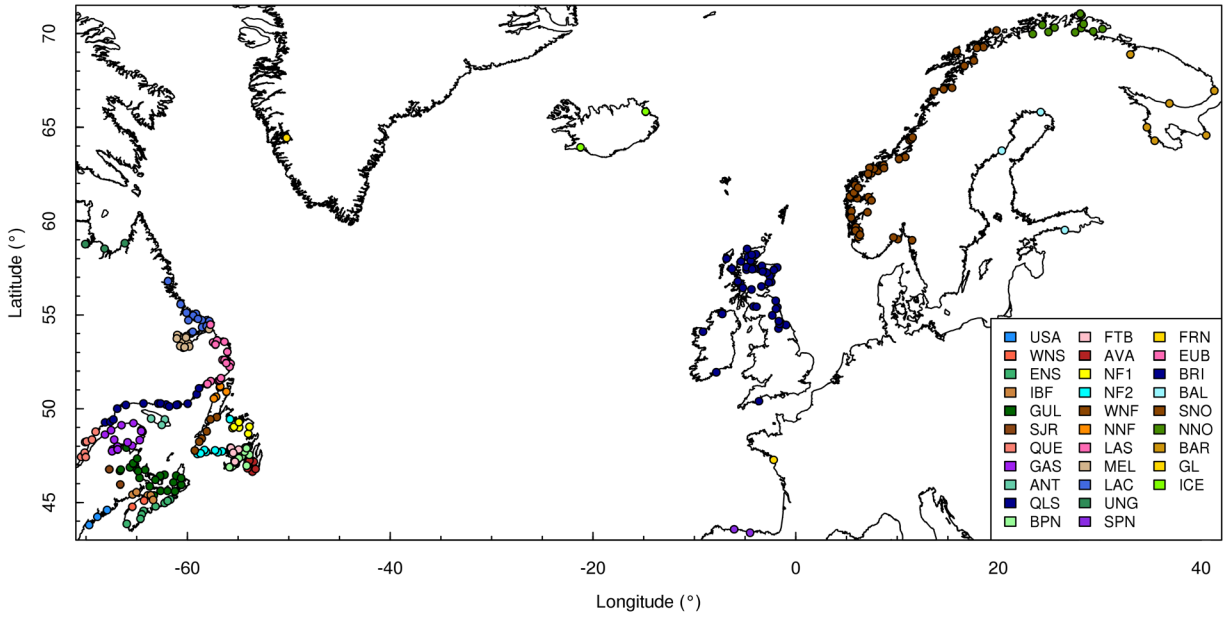

Figure 4 Map of sample locations used in the range-wide genetic baseline (single nucleotide polymorphisms [SNPs]) for Atlantic salmon, which provided 21 North America and ten European genetic reporting groups (labelled and identified by colour) and correspondence between genetic reporting groups and assessment regions for eastern North America (upper table). The EUB (European Broodstock) reporting group is not represented on the map.

Labrador fishery origin and composition of the catches

In 2019, 485 of 867 tissue samples from the Labrador subsistence salmon fisheries were analysed using the SNP panel. The percentage of the catch that was processed in 2019 for stock origin (4%) is less than the percentage of the catch sampled (6% by number); this is due to resource constraints. However, emphasis was placed on genotyping samples from the coastal areas (Salmon Fishing Areas [SFAs] 1A and 2) where interception of non-local stocks has been more prevalent in the past. As in previous years, the estimated origin of the samples was dominated (> 98%) by the Labrador genetic reporting groups. Although two samples of USA origin salmon were detected in 2017, none were detected in 2018 or in 2019. The dominance of the Labrador genetic reporting groups is consistent with previous analyses conducted for the period 2006–2018 which assigned > 95% of the harvest to Labrador groups. Assignment of harvest within the three Labrador genetic reporting groups suggest largely local harvest within salmon fishing areas (Figure 5).

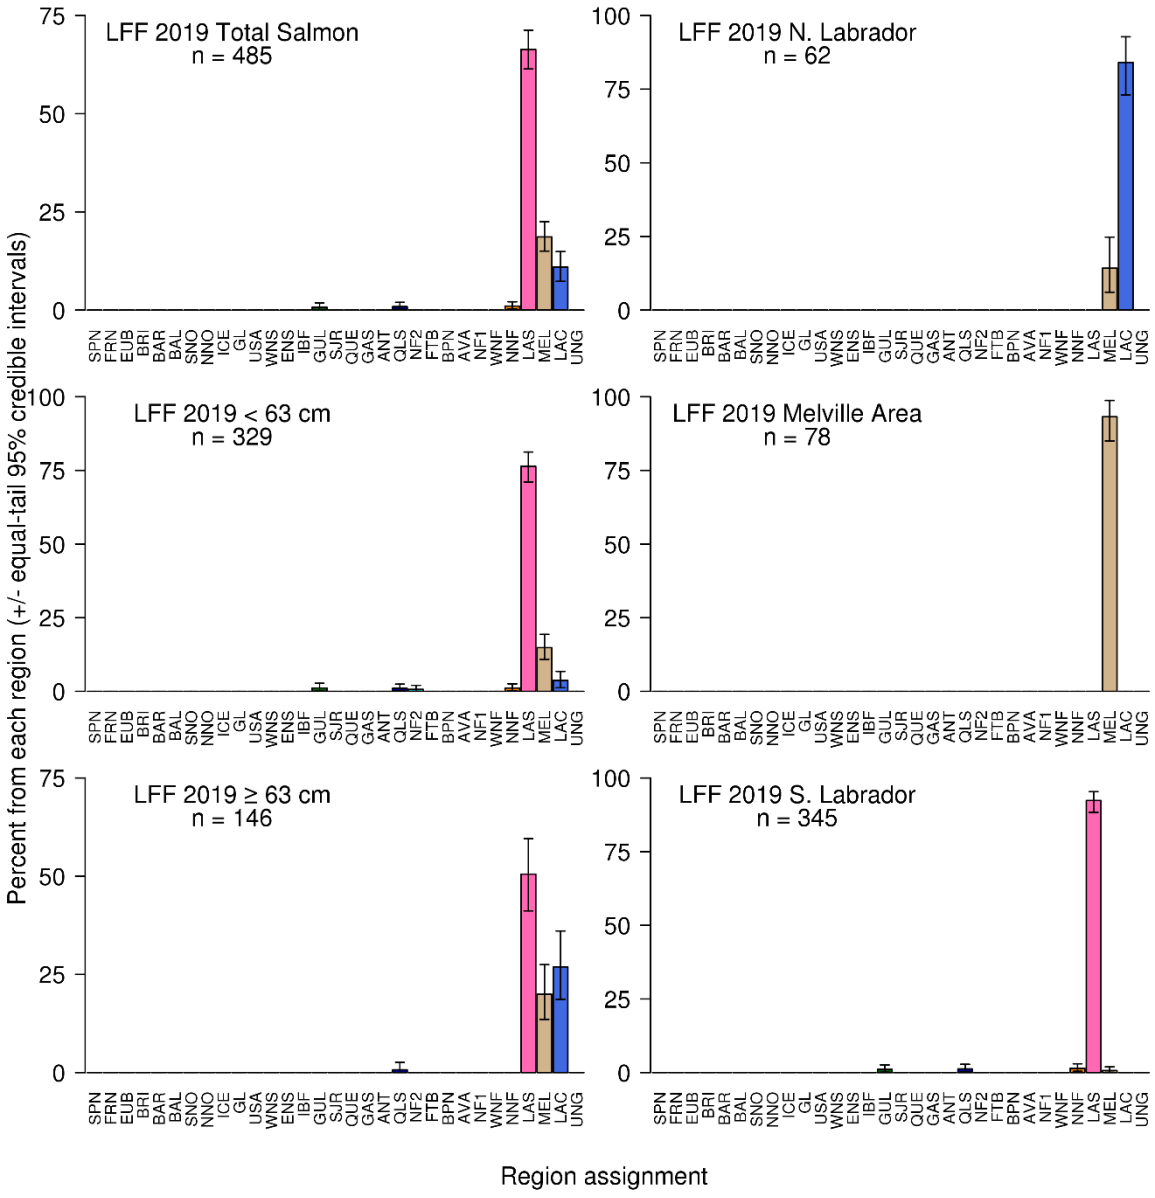

Figure 5 Percentages of Labrador subsistence fishery samples, assigned to SNP-derived regional groups of the North Atlantic for the 2019 fishery year, by size group (left) and by area (right).

Saint Pierre and Miquelon (SPM) fishery origin and composition of the catches

In 2019, 63 samples collected from the Saint Pierre and Miquelon fishery were analysed using the SNP panel range-wide baseline (12% of catch by number). Small salmon (< 63 cm fork length) represented 70% of the samples analyses, in contrast to 2017 and 2018 when samples of the catch were dominated (92% and 93%) by small salmon. Regional analysis using the SNP panel showed the consistent dominance of three genetic reporting groups; 42% Gulf of St Lawrence, 30% Gaspé Peninsula, and 24% for Newfoundland reporting groups, consistent with previous studies (ICES, 2019a; Bradbury *et al.,* 2016) (Figure 6).

The Saint Pierre and Miquelon harvest of Atlantic salmon has been dominated by small salmon in recent years (ICES, 2019a). There was no information on how the samples were collected in 2019 or if they were representative of the total catch. ICES (2018) reported on a consistent increase in the proportion of the samples assigned to the Newfoundland regional groups with increasing proportions of small salmon in the samples from the fishery, emphasizing the importance of having representative sampling of the fishery catches in order to assess the impacts of this mixed-stock fishery on stocks in North America.

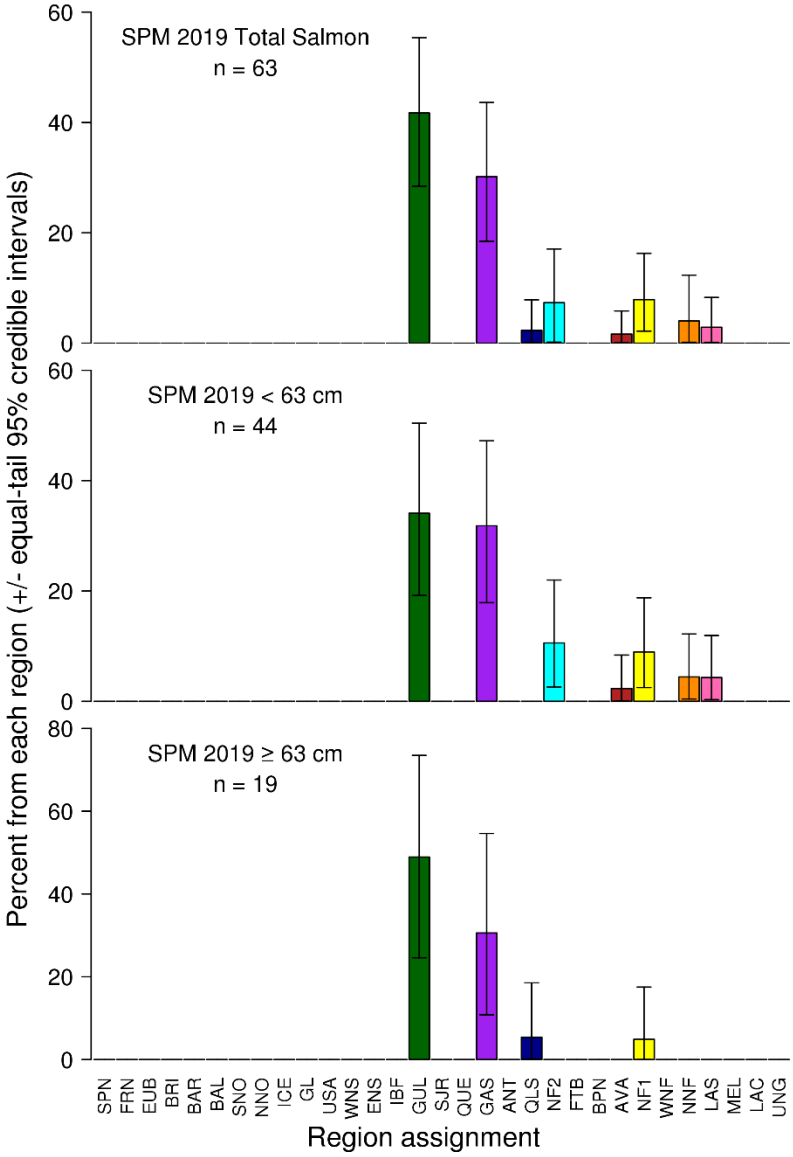

Figure 6 Percentages of the Saint Pierre and Miquelon (SPM) fishery samples assigned to SNP derived genetic reporting groups of the North Atlantic for the 2019 fishery year.

NASCO 3.2 Update age-specific stock conservation limits based on new information as available, including updating the time-series of the number of river stocks with established CLs by jurisdiction

Limit reference points were revised for some areas in North America by Fisheries and Oceans Canada (DFO, 2009; 2012; 2017; 2018) and the Province of Québec (Dionne *et al.*, 2015; MFFP, 2016). As a result of these revisions, the 2SW conservation limit (CL) for the Gulf region decreased 38% from the previous value, whereas the Québec value increased slightly (9%) (ICES, 2019a). No other changes to the 2SW CLs or the management objectives were made from those identified previously (ICES, 2015).

In addition, rebuilding management objectives have been defined for Scotia–Fundy and USA. For Scotia–Fundy, the management objective is based on an increase of 25% in returns of 2SW salmon from the mean return in the base years 1992 to 1996. For USA, the management objective is to achieve 2SW adult returns of 4549 individuals or greater (Table 3).

Table 3 2SW CLs and management objectives for the regional groups in North America in 2019.

Country and Commission area	Assessment regional group	2SW conservation limit (number of fish)	2SW Management objective (number of fish)
Canada	Labrador	34746	
	Newfoundland	4022	
	Québec	32085	
	Southern Gulf of St Lawrence	18737	
	Scotia–Fundy	24705	10976
	Total	114295	
USA		29199	4549
North American Commission		143494	

In Canada, conservation limits (CLs) were first established in 1991 for 74 rivers. Since then the number of rivers with defined CLs increased to 266 in 1997, and to 498 since 2018 (Figure 7). Conservation limits have been established for 33 river stocks in USA since 1995 (Figure 7).

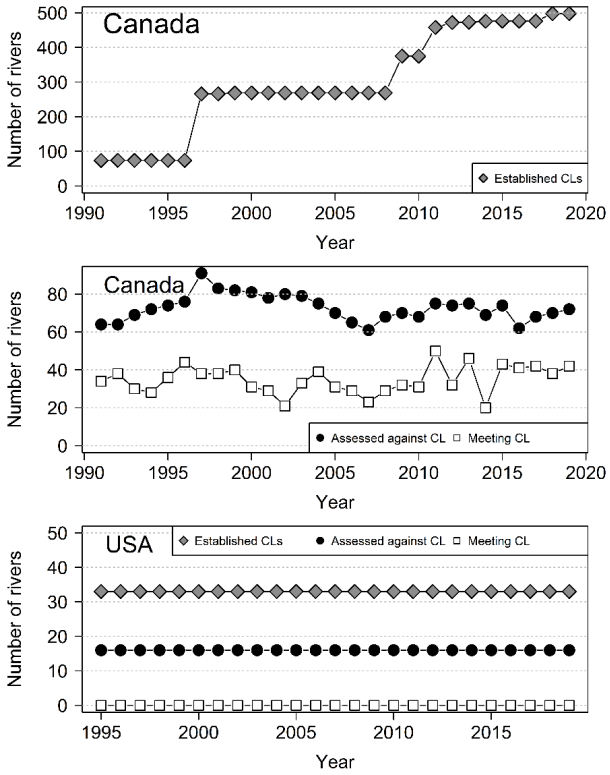

Figure 7 Time-series for Canada and the USA showing the number of rivers with established CLs, the number of rivers assessed, and the number of assessed rivers meeting CLs, for the period 1991 to 2019. Further details can be found in ICES (2020).

NASCO 3.3 Describe the status of the stocks, including updating the time-series of trends in the number of river stocks meeting CLs by jurisdiction

Stock status is presented for six assessment regions (Figure 2) and overall for North America.

Returns of small (1SW), large (MSW and repeat spawners), and 2SW salmon (a subset of large) to each region are estimated by the methods reported by ICES (1993). The 2SW component of the returns of large salmon was determined using the sea-age composition of one or more indicator stocks. Returns are the number of salmon that returned to the geographic region, including fish caught by home water commercial fisheries, except in the case of the Newfoundland and Labrador regions where returns do not include landings in commercial and subsistence fisheries.

The non-maturing component of 1SW salmon, destined to be 2SW returns (excluding 3SW and repeat spawners) is the estimated number of salmon in the North Atlantic on 1 August of their second summer at sea. The pre-fishery abundance (PFA) estimates account for returns to rivers, fisheries at sea in North America, fisheries at West Greenland, and are corrected for natural mortality. Harvests of North American origin salmon in the fishery at Faroes are not included. As the PFA estimate for potential 2SW salmon requires an estimate of returns to rivers, the most recent year for which an estimate of PFA is available is 2018. Maturing 1SW salmon are in some areas (particularly Newfoundland) a major component of salmon stocks, and their abundance when combined with that of the 2SW age group provides an index of the majority of a cohort.

The total estimate of returns of small salmon to North America in 2019 (332 100) was 22% lower than the finalized value in 2018 and the eighth lowest of the 49-year time-series (Figure 8). Returns of small salmon in 2019 decreased from the previous year in Labrador (59%) but increased in Newfoundland (81%) and Scotia–Fundy (189%). Small salmon returns in 2019 were among the lowest (third to sixth lowest of 49 years) for Québec, Gulf, and Scotia–Fundy. Returns of small salmon to Labrador (117 500) and Newfoundland (171 400) combined represented 87% of the total returns of small salmon to North America in 2019.

The total estimate of returns of large salmon to North America in 2019 (103 900) was 15% lower than in the finalized value for 2018. Returns of large salmon in 2019 decreased from the previous year in Labrador (41%), Gulf (43%), and Scotia–Fundy (52%), but increased in Québec (9%), Newfoundland (136%), and USA (109%). Large salmon returns in 2019 were the second lowest of the 49-year time-series for Gulf and Scotia–Fundy and the fourth lowest for Québec (Figure 9). Returns of large salmon to Labrador (27 100), Québec (31 000), and Gulf (19 700) combined represented 75% of the total returns of large salmon to North America in 2019.

The total estimate of 2SW salmon returns (subset of returns of large salmon) to North America in 2019 (59 900) was 28% lower than in 2018 (82 900; Figure 10). The 2SW salmon returns to NAC in 2019 were the second lowest on record (49 years), and were particularly low in Québec (fourth lowest), Gulf, and Scotia–Fundy (second lowest). Although the estimated 2SW returns in Labrador were thirteenth highest in the 49-year time-series, the returns were the second lowest of the most recent ten years. Three assessment regions (Labrador, Québec, and Gulf) collectively accounted for 92% of the returns of 2SW salmon to North America in 2019.

In 2019, the estimates (median) of 2SW salmon returns to rivers and spawners were below CLs (suffering reduced reproductive capacity) in all six assessment regions; the percentages of respective 2SW CLs attained by spawners ranged from 3% in Scotia–Fundy to 77% in the Gulf (Figure 11). Particularly large deficits relative to CLs and rebuilding management objectives are noted in the Scotia–Fundy and USA regions.

River-specific assessments are provided for 86 rivers in 2019. Egg depositions by all sea ages combined in 2019 exceeded or equaled the river-specific CLs in 42 of the 86 assessed rivers (49%) and were at or less than 50% of CLs in 28 rivers (33%) (Figure 12). The number of rivers assessed annually in Canada has ranged from 61 to 91, and the annual percentages of these rivers achieving CL has ranged from 26% to 67% (59% in 2019) with no temporal trend (Figure 7). Sixteen rivers in the USA are assessed against CL attainment annually, with none meeting CLs to date (Figure 7).

Estimates of PFA (defined as the number of maturing and non-maturing 1SW salmon) suggest continued low abundance of North American salmon (Figure 10). The PFA in the Northwest Atlantic has oscillated around a generally declining trend since the 1970s, with a period of persistent low abundance since the early 1990s. During the period 1993 to 2018, the PFA averaged 605 000 fish, less than half of the average abundance (1 232 000 fish) during the period 1971 to 1992. The PFA of maturing and non-maturing 1SW salmon in 2018 was estimated at 551 700 fish. Abundance declined by 66% over the time-series, from a peak of 1 705 000 fish in 1975 (Figure 13).

Despite major changes in fisheries management two to three decades ago, and increasingly more restrictive fisheries measures since then, returns of salmon have remained near historical lows, with the exception of those in Labrador and Newfoundland. All salmon populations within USA and the Scotia–Fundy regions have been, or are being considered for, listing under country-specific species-at-risk legislation. The continued low abundance of salmon stocks in USA and in three regions of Canada (Scotia–Fundy, Gulf, and Québec), despite significant fishery reductions, strengthens the conclusions that factors acting on survival in the first and second years at sea at both local and broad ocean scales are constraining the abundance of salmon. Declines in smolt production in some rivers of eastern North America are now being observed and may also be contributing to lower adult abundance.

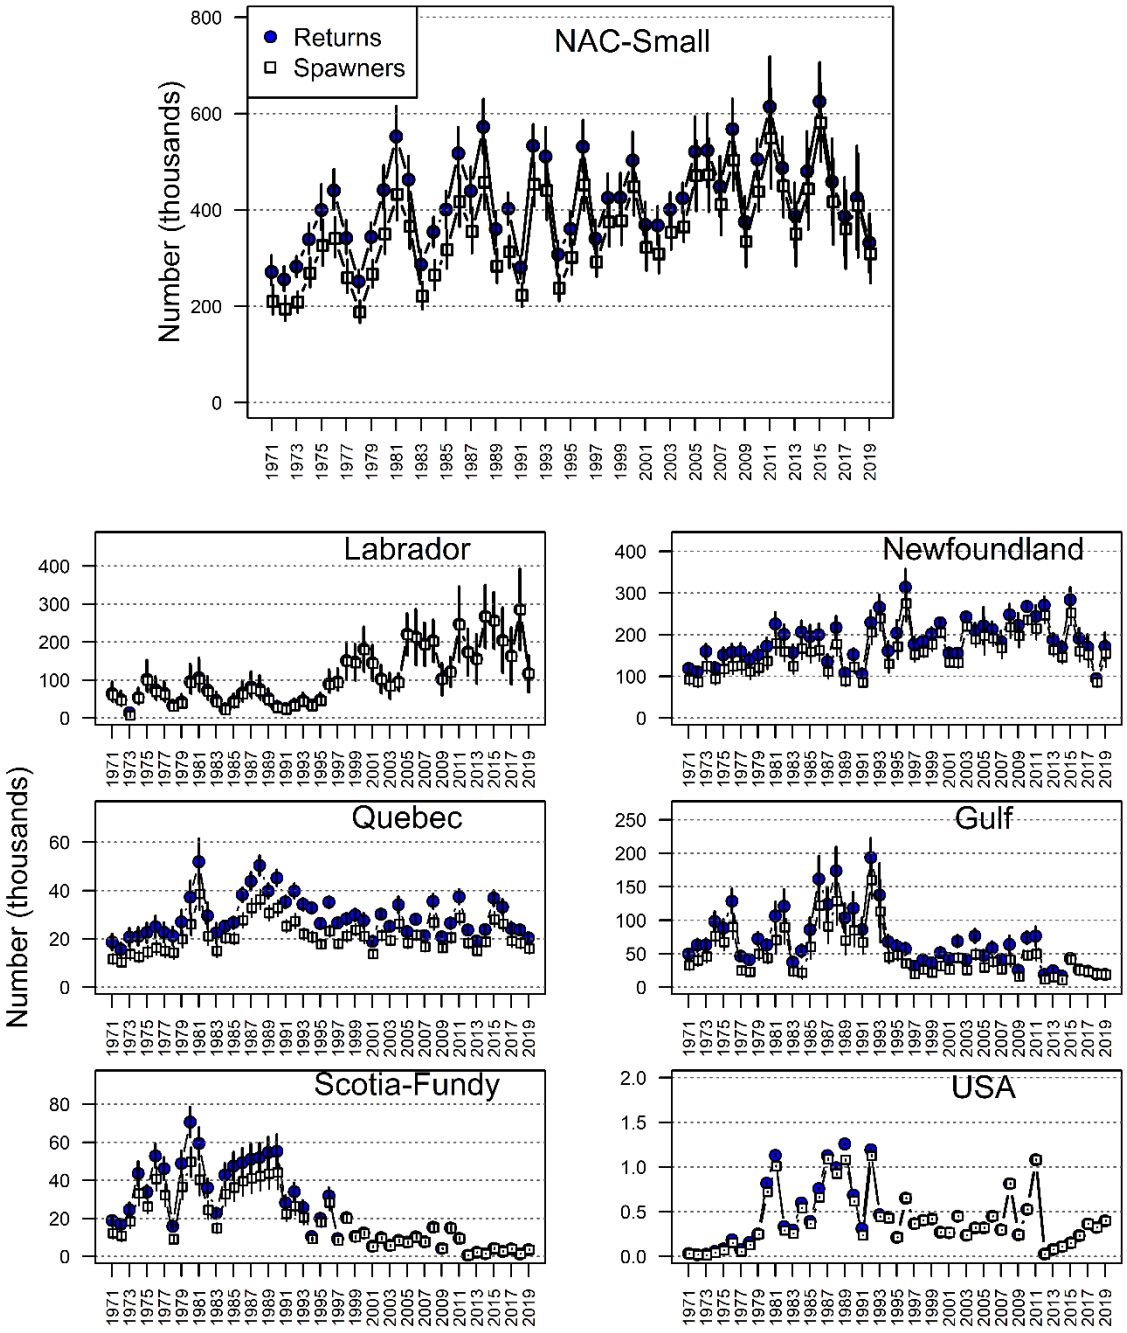

Figure 8 Estimated (median, 5th to 95th percentile range) returns (shaded circles) and spawners (open squares) of small salmon (primarily 1SW) for eastern North America overall and for each of the six regions, 1971 to 2019.

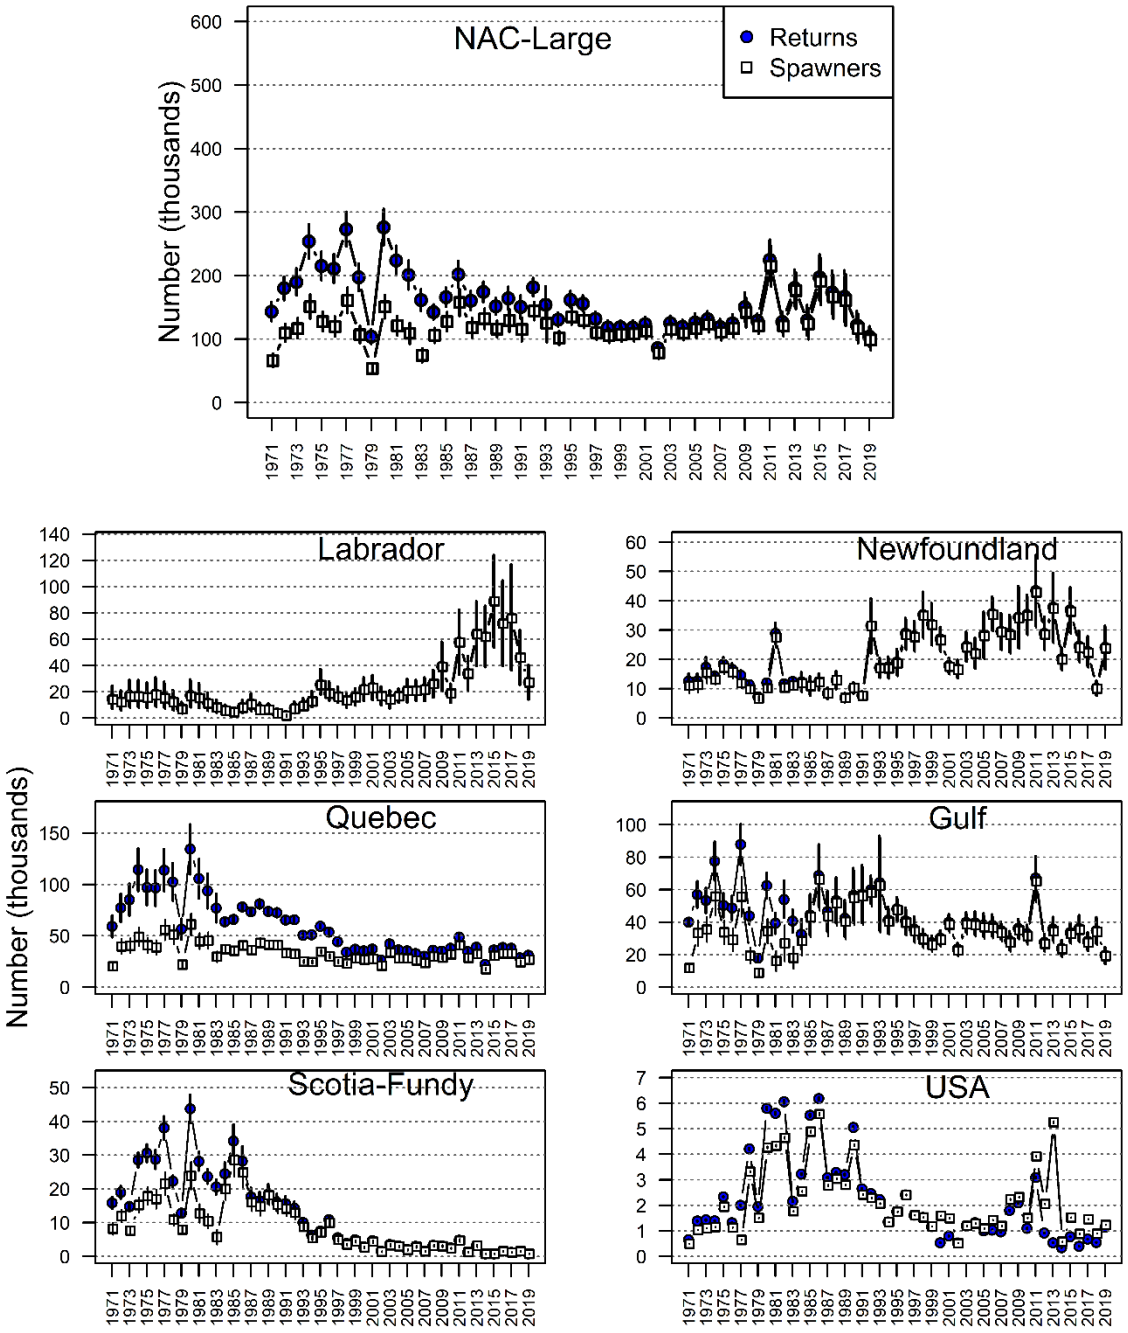

Figure 9 Estimated (median, 5th to 95th percentile range) returns (shaded circles) and spawners (open squares) of large salmon (primarily MSW and repeat spawners) for eastern North America overall and for each of the six regions, 1971 to 2019.

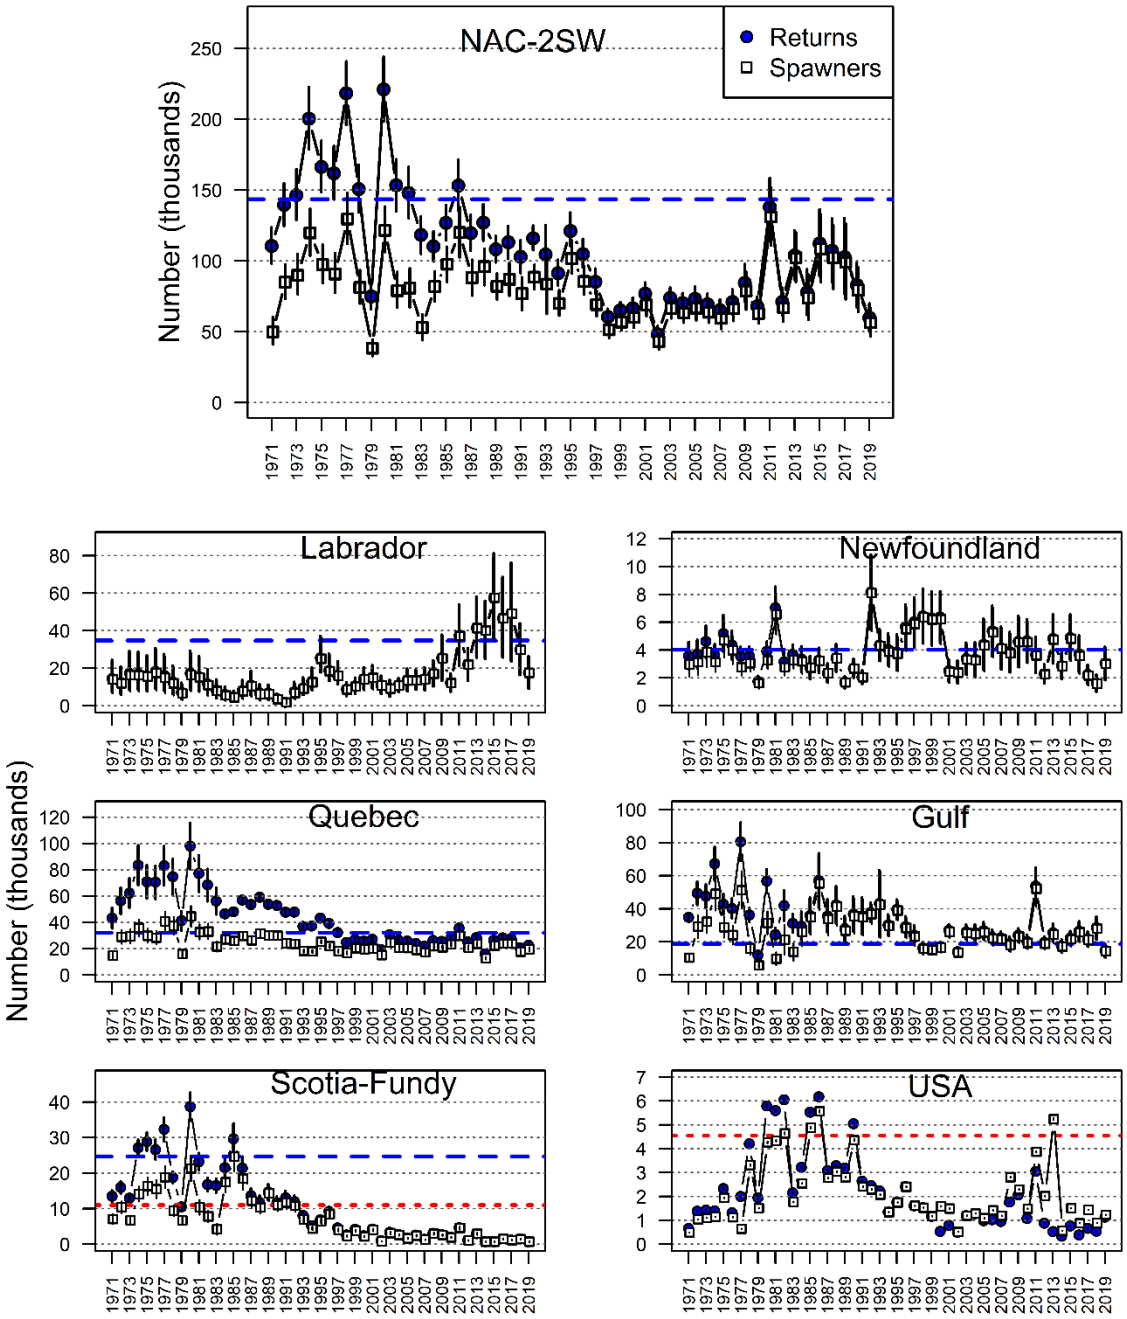

Figure 10 Estimated (median, 5th to 95th percentile range) returns (shaded circles) and spawners (open squares) of 2SW salmon for eastern North America overall and for each of the six regions. The dashed line is the corresponding 2SW CL; the 2SW CL (29 199 fish) is off scale in the plot for USA. The dotted lines in the Scotia–Fundy and USA panels are the region-specific management objectives. For USA, estimated spawners exceed the estimated returns in some years as a result of adult stocking restoration efforts, 1971 to 2019.

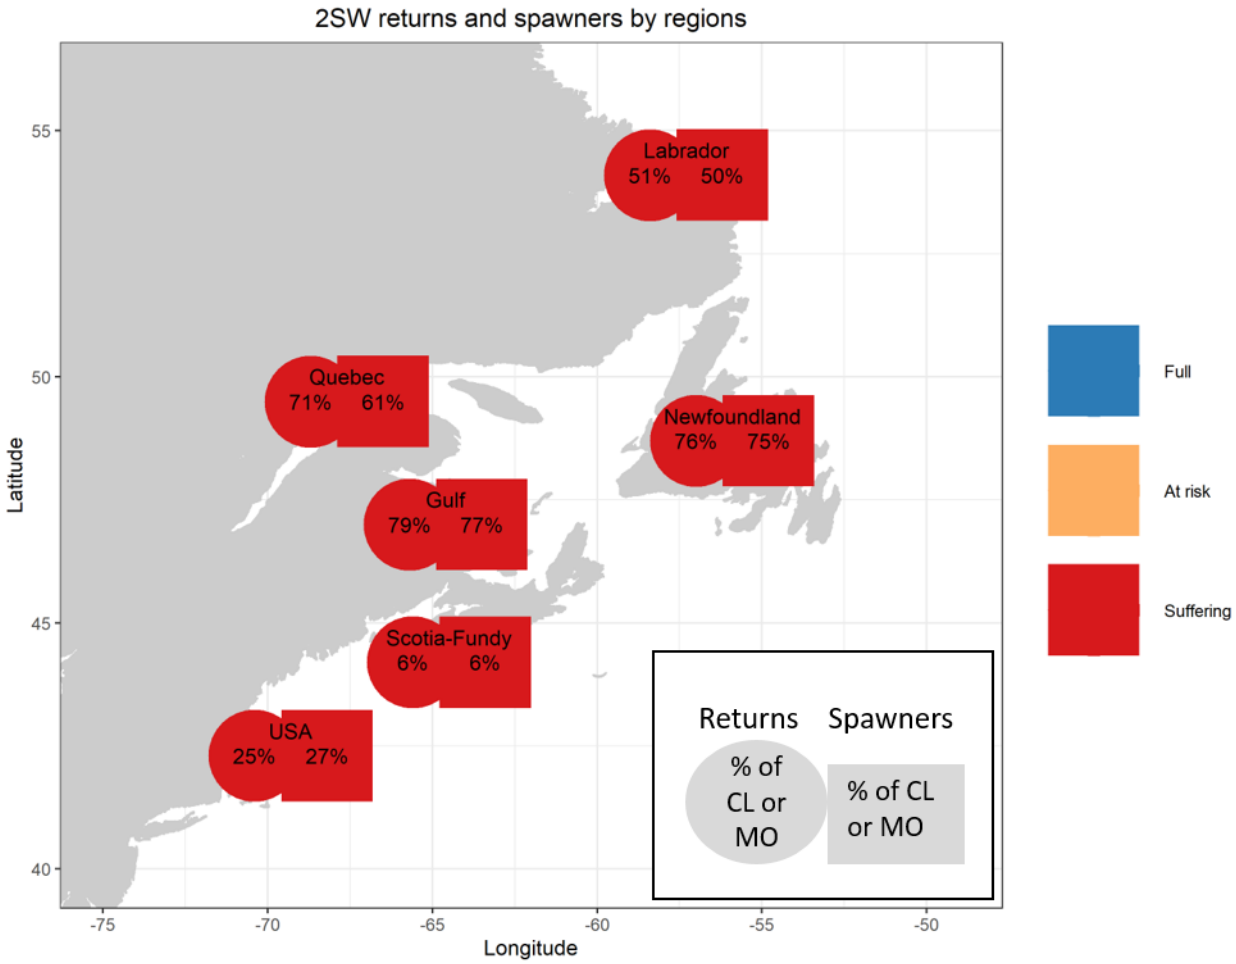

Figure 11 Estimated returns (circle symbol) and spawners (square symbol) of 2SW salmon in 2019 to six regions of North America relative to the stock status categories. The percentage of the 2SW CLs for the four northern regions and to the rebuilding management objectives (MO) for the two southern areas are shown based on the median of the Monte Carlo distribution. The colour shading, which in this case is relevant for red only as all stocks in these regions are categorized as suffering reduced reproductive capacity, is interpreted as follows: blue refers to the stock being at full reproductive capacity (median and 5th percentile of the Monte Carlo distributions are above the CL), orange refers to the stock being at risk of suffering reduced reproductive capacity (median is above but the 5th percentile is below the CL), and red refers to the stock suffering reduced reproductive capacity (the median is below the CL).

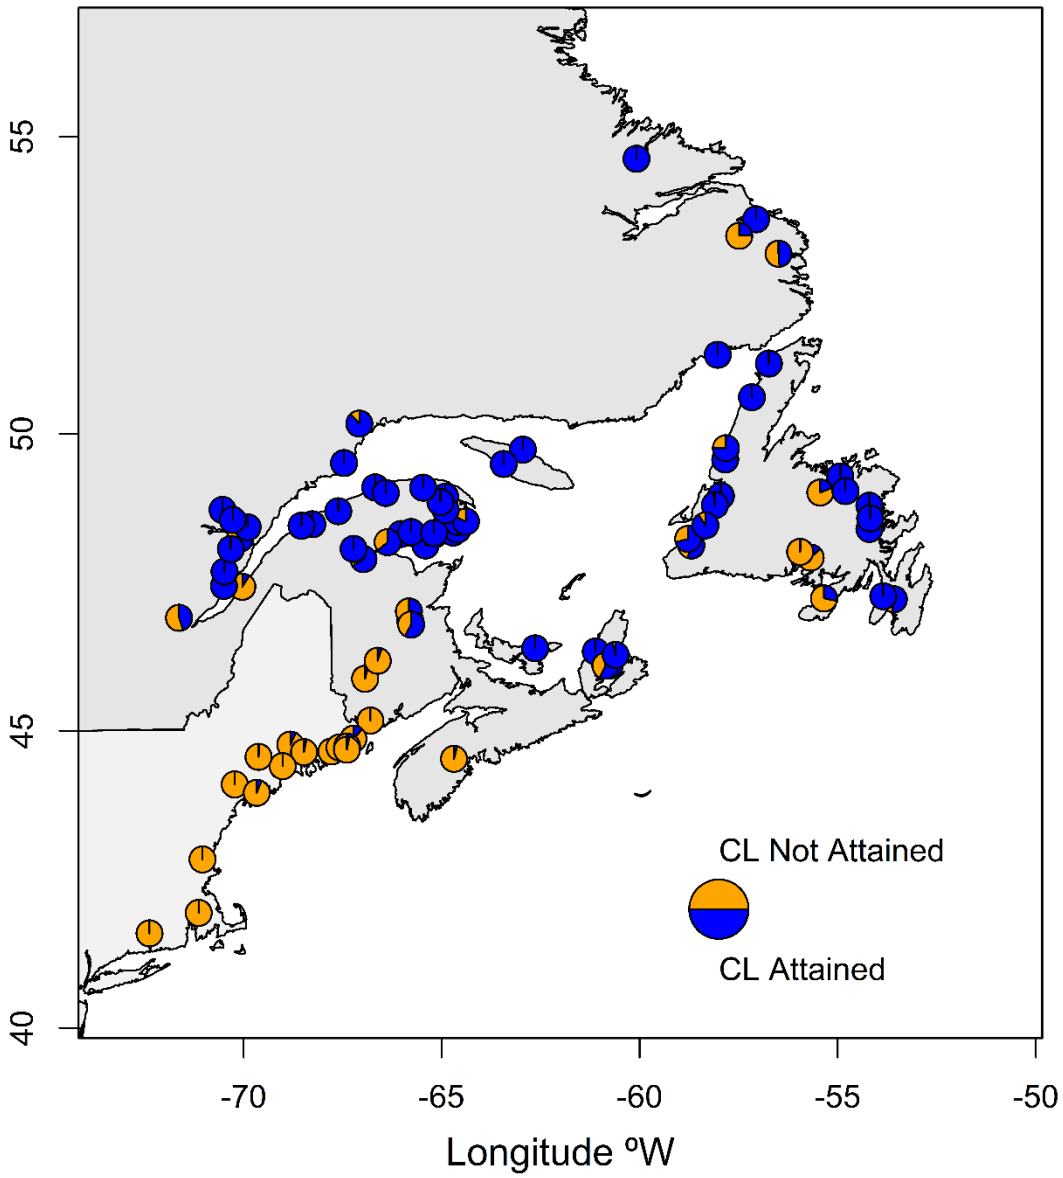

Figure 12 Degree of attainment for the river-specific conservation egg requirement (CL) in the 86 rivers of the North American Commission area assessed in 2019. Three rivers in the USA are not shown because they were partially assessed, but they are considered not to have attained CLs in 2019.

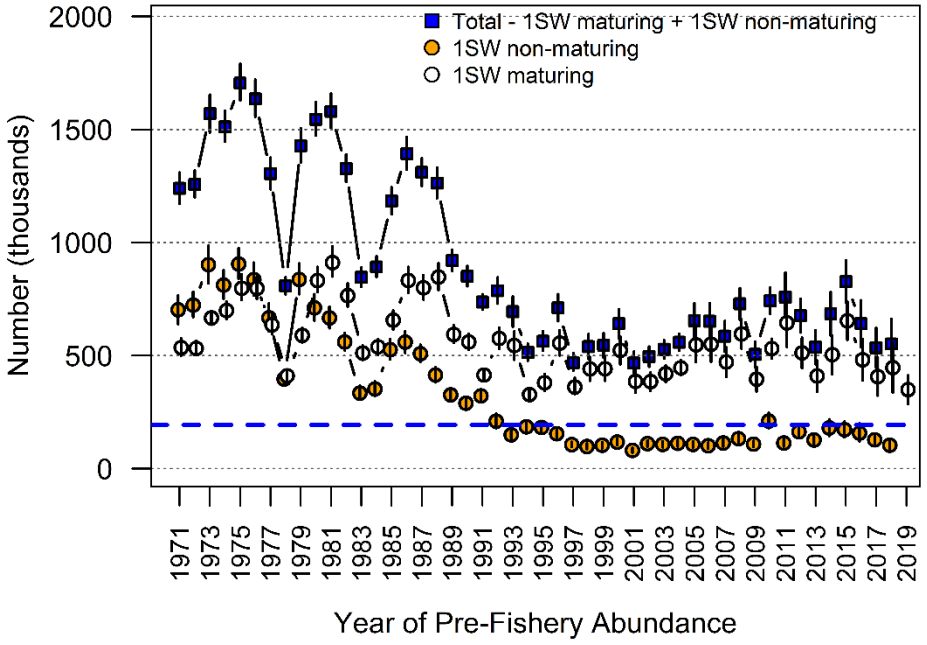

Figure 13 Estimated (median, 5th to 95th percentile range) pre-fishery abundance (PFA) for 1SW maturing, 1SW non-maturing, and total cohort of 1SW salmon for North America. The dashed blue horizontal line is the corresponding sum of the 2SW conservation limits for North America, corrected for 11 months of natural mortality, against which 1SW non-maturing abundance is assessed.

Annex 1 Glossary of acronyms and abbreviations

1SW *(one-sea-winter).* Maiden adult salmon that have spent one winter at sea.
2SW *(two-sea-winter).* Maiden adult salmon that have spent two winters at sea.
3SW *(three-sea-winter).* Maiden adult salmon that have spent three winters at sea.
CL, i.e. S_{lim} *(conservation limit).* Demarcation of undesirable stock levels or levels of fishing activity; the ultimate objective when managing stocks and regulating fisheries will be to ensure that there is a high probability that undesirable levels are avoided.
FWI *(Framework of Indicators).* The FWI is a tool used to indicate if any significant change in the status of stocks used to inform the previously provided multi-annual management advice has occurred.
ICES (*International Council for the Exploration of the Sea*).
NAC (*North American Commission*). A commission under NASCO.
NASCO (*North Atlantic Salmon Conservation Organization*).
PFA *(pre-fishery abundance).* The numbers of salmon estimated to be alive in the ocean from a particular stock at a specified time.
SFA (*Salmon Fishing Area*). The 23 areas for which Fisheries and Oceans Canada (DFO) manages the salmon fisheries.
SPM (*the islands of Saint Pierre and Miquelon [France]*).

Annex 2* General considerations

Management plans

The North Atlantic Salmon Conservation Organization (NASCO) has adopted an Action Plan for Application of the Precautionary Approach, which stipulates that management measures should be aimed at maintaining all stocks above their conservation limits through the use of management targets. NASCO has adopted the region-specific CLs as limit reference points (S_{lim}); having populations fall below these limits should be avoided with high probability. Within the agreed management plan for the North American Commission, the following has been agreed for the provision of catch advice on 2SW salmon exploited in North America (as non-maturing 1SW and 2SW salmon): a risk level (probability) of 75% for simultaneous attainment of the 2SW CLs for the four northern regions (Labrador, Newfoundland, Québec, Gulf), management objectives defined as achieving a 25% increase in 2SW returns relative to a baseline period (average returns in the period 1992–1996) for the Scotia–Fundy region, and the achievement of 2SW adult returns of 4549 fish or greater. A framework of indicators has been developed to identify any significant change in the multi-annual management advice in the intervening years of the three-year assessment cycle.

Biology

Atlantic salmon (*Salmo salar*) is an anadromous species found in rivers of countries bordering the North Atlantic. In the Northwest Atlantic they range from the Connecticut River (USA, 41.6°N) northward to the Ungava Bay rivers (58.8°N; Québec, Canada). Juveniles emigrate to the ocean at ages of one to eight years (dependent on latitude) and generally return after one or two years at sea. Long-distance migrations to ocean feeding grounds are known to take place, with adult salmon from both the North American and Northeast Atlantic stocks migrating to West Greenland to feed in their second summer and autumn at sea. Recent genetic information has demonstrated that fish from North America were also exploited in the historical Faroes fishery.

Environmental influence on the stock

Environmental conditions in both freshwater and marine environments have a marked effect on the status of salmon stocks. Across the North Atlantic, a range of problems in the freshwater environment play a significant role in explaining the poor status of stocks. In many cases, river damming and habitat deterioration have had a devastating effect on freshwater environmental conditions. In the marine environment, return rates of adult salmon have declined through the 1980s and are now at the lowest levels in the time-series for some stocks, even after closure of marine fisheries. Climatic factors modifying ecosystem conditions and the impact of predators of salmon at sea are considered to be the main contributory factors to lower productivity, which is expressed almost entirely in terms of lower marine survival.

Effects of the fisheries on the ecosystem

The current salmon fisheries probably have no influence, or only a minor influence, on the marine ecosystem. However, the exploitation rate on salmon may affect the riverine ecosystem through changes in species composition. Knowledge on the magnitude of these effects is limited.

Quality considerations

Uncertainties in input variables to the stock status and stock forecast models are incorporated in the assessment. The reliability of catch statistics could be improved in all North America. Estimates of abundance of adult salmon in some areas, in particular Labrador, are based on a small number of counting facilities raised to a large production area.

* Version 2: All text prior to Scientific basis table inserted

Scientific basis

ICES stock data category	1 (ICES, 2019b).
Assessment type	Run-reconstruction models and Bayesian forecasts, taking into account uncertainties in the data.
Input data	Nominal catches (by sea-age class) for commercial, indigenous, and recreational fisheries. Estimates of unreported/illegal catches. Estimates of exploitation rates. Natural mortalities (from earlier assessments).
Discards and bycatch	It is illegal to retain salmon that are incidentally captured in fisheries not directed at salmon (no bycatch). In the directed recreational fishery, mortality from catch and release is accounted for in the regional assessments to estimate spawners. There is no accounting of discarding mortality in non-salmon directed fisheries.
Indicators	The Framework of Indicators is used to indicate whether a significant change has occurred in the status of stocks in intermediate years where multiannual management advice applies.
Other information	Advice subject to annual review. A stock annex was developed in 2014 and updated in 2019 (ICES, 2019c).
Working group	Working Group on North Atlantic Salmon (WGNAS) (ICES, 2020).

Atlantic salmon at West Greenland

Summary of the advice for 2020

ICES advises that when the Framework of Indicators (FWI) was applied in early 2020, a full reassessment was not required and the 2018 ICES advice remains valid (ICES, 2018). Consequently, in line with the management objectives agreed by the North Atlantic Salmon Conservation Organization (NASCO) and consistent with the MSY approach, there are no mixed-stock fishery options at West Greenland for the fishing year 2020. 2020 marks the final year of NASCO's three-year multi-annual regulatory measure for fishing Atlantic salmon at West Greenland (NASCO, 2018).

NASCO 4.1 Describe the key events of the 2019 fishery, including details of catch, gear, effort, composition and origin of the catch, rates of exploitation, and location of the catch as in-river, estuarine, and coastal

Fishing for salmon at Greenland is currently allowed, using hook, fixed gillnets, and driftnets along the entire coast (Figure 1). The commercial fishery for export closed in 1998; the fishery for internal use, however, continues to date. Since 2002, licensed commercial fishers have only been allowed to sell salmon to hotels, institutions, local markets, and factories when factory landings were allowed. People fishing for private consumption only were not required to have a licence until 2018, and are prohibited from selling salmon. The Government of Greenland unilaterally set the quotas for the fisheries from 2012 to 2017 (Table 1). Specific annual factory quotas were set at 35 tonnes (t) for 2012 and 2013, and 30 t in 2014. Licensed fishers were permitted to sell to factories during these years, although the export ban persisted. The Government of Greenland set annual quotas for the 2015–2017 fisheries for all components of the fishery (private, commercial, and factory landings) at 45 t, but stated that any overharvest in a particular year would result in an equal reduction in the quota the following year. As a result of an overharvest in 2015, the 2016 quota was set at 32 t by Greenland. The quota for 2017 remained at 45 t. Factory landings were not permitted in 2016 and 2017.

In 2018, the Government of Greenland set an annual quota for the 2018–2020 fisheries to 30 t, as agreed by all parties of the West Greenland Commission of NASCO. A 10 t quota was allocated for the private fishery, with the balance (20 t) for the commercial fishery. Within the regulatory measure, the Government of Greenland agreed to continue its ban on the export of both wild Atlantic salmon and its products from Greenland, and to prohibit landings and sales to fish-processing factories. As in the previous agreement, they also agreed the fishery should be restricted to run from 15 August to no later than 31 October each year, and that any overharvest in a particular year would result in an equal reduction in the total allowable catch in the following year. The regulatory measure also set out a number of provisions aimed at improving the monitoring, management control, and surveillance of the fishery. These include a new requirement for all fishers (private and commercial) to obtain a licence to fish for Atlantic salmon, an agreement to collect catch and fishing activity data from all fishers, and mandatory reporting requirements. The measure also stated that as a condition of the licence, all fishers would be required to allow samplers from the NASCO sampling programme to take samples of their catches upon request.

Catches of Atlantic salmon at West Greenland (Figure 2 and Table 1) increased through the 1960s, reached a peak in reported harvest of approximately 2700 t in 1971, and then decreased until the closure of the commercial fishery for export in 1998. Catches are reported from all six NAFO divisions, and proportions vary annually (Table 2). A total salmon catch of 29.8 t was reported for the 2019 fishery, a decrease from the 2018 catch (39.9 t), but an overharvest of 10.3 t over the 19.5 t quota (Table 2). The 2019 quota was reduced from 30 t to 19.5 t due to overharvest in 2018. In 2019, commercial landings represented the majority of the harvest at 22.0 t (74.0%) and the remaining 7.7 t was for private use, compared to 32.5 t and 7.4 t, respectively in 2018 (Table 3). In 2018 and 2019, the percentage of commercial landings reported for private use dropped to 0.4% and 0.3%, respectively, compared to an average of 44% from 1997 to 2017. Reported commercial and private landings by NAFO/ICES areas in 2019 are presented in Table 4. The number of licences issued, the number of fishers who reported, and the number of reports received have increased greatly since 2017, a result of both the new regulations requiring all fishers to obtain a licence and the mandatory reporting requirements.

The fishery was closed on 25 September 2019 as 19.5 t of landings had been registered; this number was later revised to 29.8 t, resulting in an overharvest of 10.3 t for the 2019 fishery. The Greenlandic authorities indicated a further 10 t of unreported harvest.

An adjustment for some of the unreported catch has been carried out since 2002 by two approaches: comparisons of the sampling programme statistics and reported landings (adjusted landings [survey]), and utilizing results from the previously implemented phone surveys (adjusted landings [sampling]). Adjusted landings (sampling) are estimated by comparing the weight of salmon observed by the sampling teams and the corresponding community-specific reported landings for the entire fishing season. Sampling is not random and only occurs during part of the fishing season; it is therefore not representative of the total unreported catch. Adjusted landings (survey) are estimated from results of phone surveys, conducted after the fishing seasons 2014 to 2016, to gain further information on inconsistencies in the reported catch data. Adjusted landings (survey) are added to the adjusted landings (sampling) and reported landings to estimate the landings for assessment. Landings for assessment do not replace the official reported statistics (Table 5).

The international sampling programme continued in 2019 (Figure 1). A summary of the biological characteristics of the 2019 catch is presented in Table 6. In 2019, 71.5% of the salmon sampled were determined to be of North American origin and 28.5% of European origin (Figure 3); approximately 6800 (20.3 t) North American and 2600 (8.1 t) fish of European origin were harvested in 2019 (Figure 4). The total number of fish harvested in 2019 (9400) is a decrease from the estimated number harvested in 2018 (13 200). The origin of salmon harvested at West Greenland in 2019 has been estimated based on an updated genetic range-wide baseline (using Single Nucleotide Polymorphisms [SNPs]). This baseline, based on samples from 189 rivers (Jeffery *et al*., 2018), was updated in 2018 (ICES, 2018) and can discriminate salmon from 21 North American and 10 European genetic reporting groups (Figure 5). The North American contributions to the West Greenland fishery are dominated by the Gaspé Peninsula, Gulf of St Lawrence, and Labrador South genetic reporting groups (65%; Table 7). The Northeast Atlantic contributions were dominated by the United Kingdom/Ireland genetic reporting group (99%). There are smaller, but consistent contributions to the harvest for a number of other genetic reporting groups. Results are similar to those reported for the 2017 and 2018 fisheries (ICES, 2019a, 2019b). A single sample, based on the individual assignment method, was identified as having originated from the Greenland genetic reporting group (Kapisillit River) in 2018, but no samples were identified in 2019.

Table 1 Nominal catches of salmon at West Greenland since 1960 (tonnes, round fresh weight) by participating nations. For Greenlandic vessels specifically, all catches up to 1968 were taken with set gillnets only, and catches after 1968 were taken with set gillnets and driftnets. All non-Greenlandic vessel catches from 1969 to 1975 were harvested with driftnets. The quota figures applied to Greenlandic vessels only, and parenthetical entries identify when quotas did not apply to all sectors of the fishery.

2008	-	-	-	-	26	26		Same as previous year.
2009	-	-	-	-	26	26		Same as previous year.
2010	-	-	-	-	40	40		No factory landings allowed and fishery restricted to catches used for internal consumption in Greenland.
2011	-	-	-	-	28	28		Same as previous year.

Year	Norway	Faroes	Sweden	Denmark	Greenland	Total	Quota	Comments
2012	-	-	-	-	33	33	(35)	Unilateral decision made by Greenland for a 35 t quota for factory landings only; fishery restricted to catches used for internal consumption in Greenland, and higher catch figures based on sampling programme information are used for the assessments.
2013	-	-	-	-	47	47	(35)	Same as previous year.
2014	-	-	-	-	58	58	(30)	Unilateral decision made by Greenland to allow factory landings with a 30 t quota for factory landings only; fishery restricted to catches used for internal consumption in Greenland, and higher catch figures based on sampling programme information and phone surveys are used for the assessments.
2015	-	-	-	-	57	57	45	Unilateral decision made by Greenland to set a 45 t quota for all sectors of the fishery; fishery restricted to catches used for internal consumption in Greenland, and higher catch figures based on sampling programme information and phone surveys are used for the assessments.
2016	-	-	-	-	27	27	32	Unilateral decision made by Greenland to reduce the previously set 45 t quota for all sectors of the fishery to 32 t based on the average of the 2015 fishery; fishery restricted to catches used for internal consumption in Greenland, and higher catch figures based on sampling programme information and phone surveys are used for the assessments.
2017	-	-	-	-	28	28	45	Unilateral decision made by Greenland to set a 45 t quota for all sectors of the fishery; fishery restricted to catches used for internal consumption in Greenland, and higher catch figures based on sampling programme information are used for the assessments.
2018	-	-	-	-	40	40	30	No factory landings allowed and fishery restricted to catches used for internal consumption in Greenland.
2019	-	-	-	-	30	30	19.5	No change from previous year.

Table 2 Annual distribution of nominal catches (t) at Greenland by NAFO division (when known). NAFO divisions are shown in Figure 2. Since 2005, gutted weights have been reported and converted to total weight by a factor of 1.11. Rounding issues are evident for some totals.

Year	NAFO Division						Unknown	West Greenland	East Greenland	Total

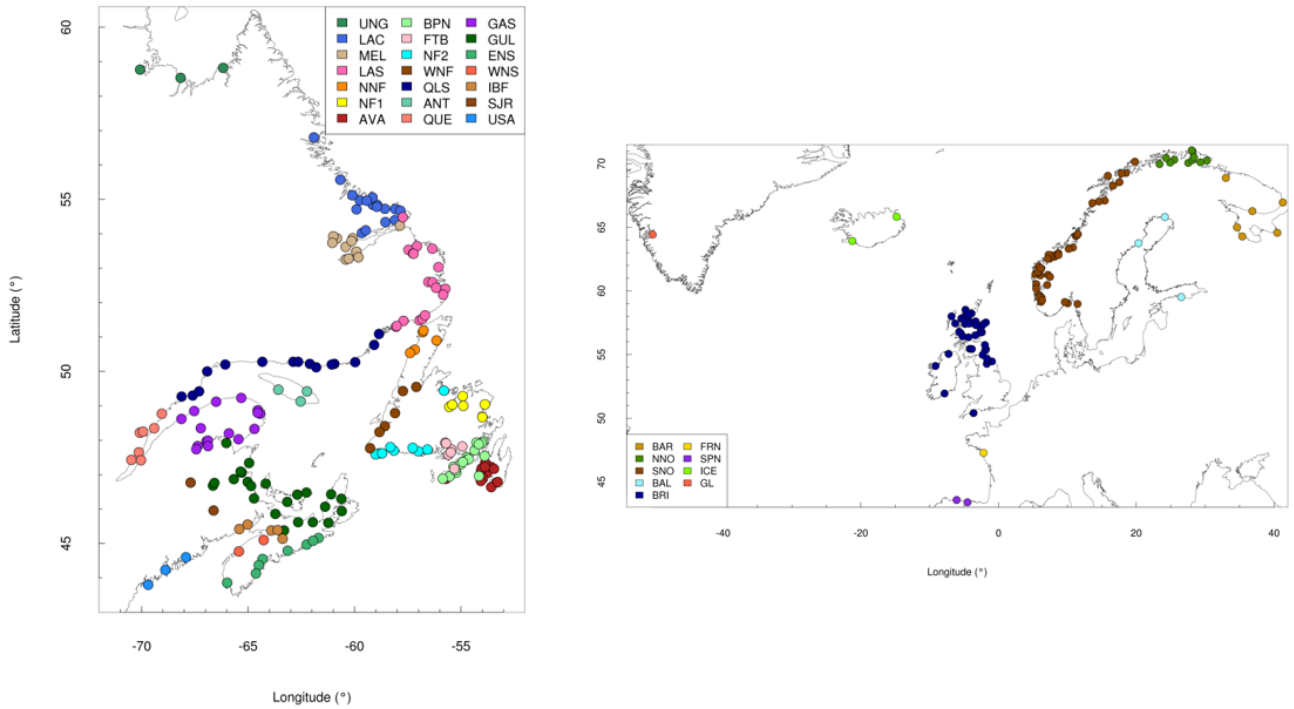

Figure 5* Regional group and codes from the SNP-based genetic baseline (upper table) and location maps for North America (left) and Europe (right). The EUB (European broodstock) regional group does not have a geographic location and therefore is not represented on the map.

* Version 2: Figure updated.

NASCO 4.2 Describe the status of the stocks

Recruitment (pre-fishery abundance) estimates of non-maturing 1SW salmon at Greenland show continued low abundance compared to historical levels and are currently below the spawner escapement reserves (SER) for the North American Commission (NAC; Figure 6) and Southern NEAC (Figure 7) stock complexes.

In 2019, the median estimates of spawners were below the conservation limits (CLs; suffering reduced reproductive capacity) for 2SW salmon in all six regions of NAC, and for MSW salmon in Southern NEAC (Figure 8). Particularly large deficits relative to CLs and rebuilding management objectives are noted in the NAC Scotia–Fundy and USA regions.

The exploitation rate (catch in Greenland divided by pre-fishery abundance [PFA]) in 2018 was 12.9% for NAC fish and 0.7% for Southern NEAC fish (Figure 9). Despite major changes in fisheries management in the past few decades and increasingly more restrictive fisheries measures, returns have remained near historical lows. It is likely, therefore, that other factors besides fisheries are constraining production.

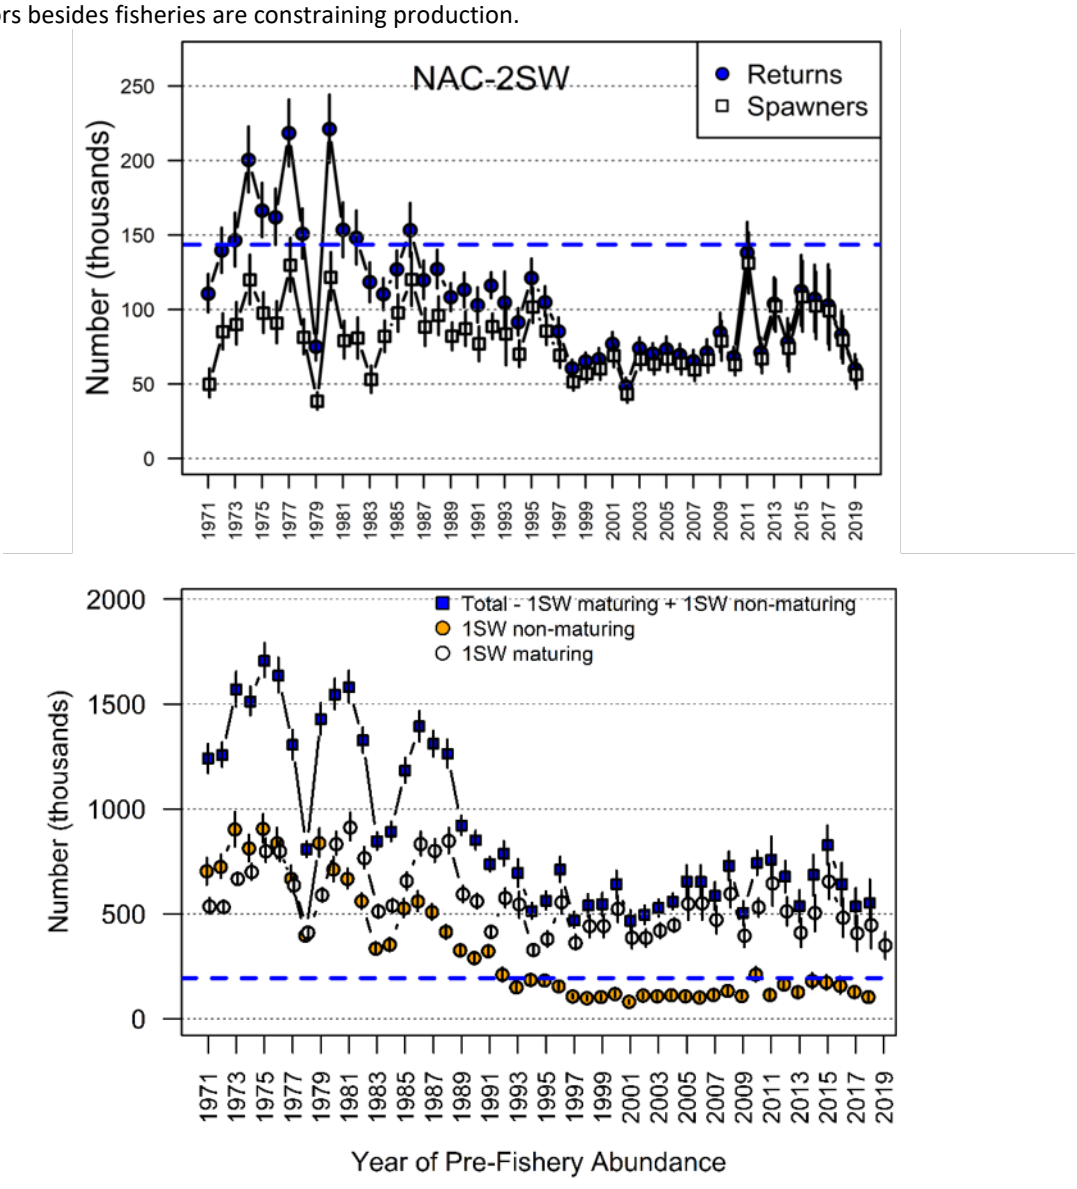

Figure 6 Top panel: Estimated (median, 5th to 95th percentile range, in thousands) returns (blue circles) and spawners (white squares) of 2SW salmon for NAC, 1971–2019. The dashed line is the corresponding 2SW conservation limit for NAC. Bottom panel: Estimated (median, 5th to 95th percentile range, in thousands) pre-fishery abundance (PFA) for 1SW maturing, 1SW non-maturing, and the total cohort of 1SW salmon for NAC, PFA years 1971–2018. The dashed blue horizontal line is the corresponding sum of the 2SW conservation limits for NAC (143 494), corrected for 11 months of natural mortality (193 697) against which 1SW non-maturing salmon are assessed.

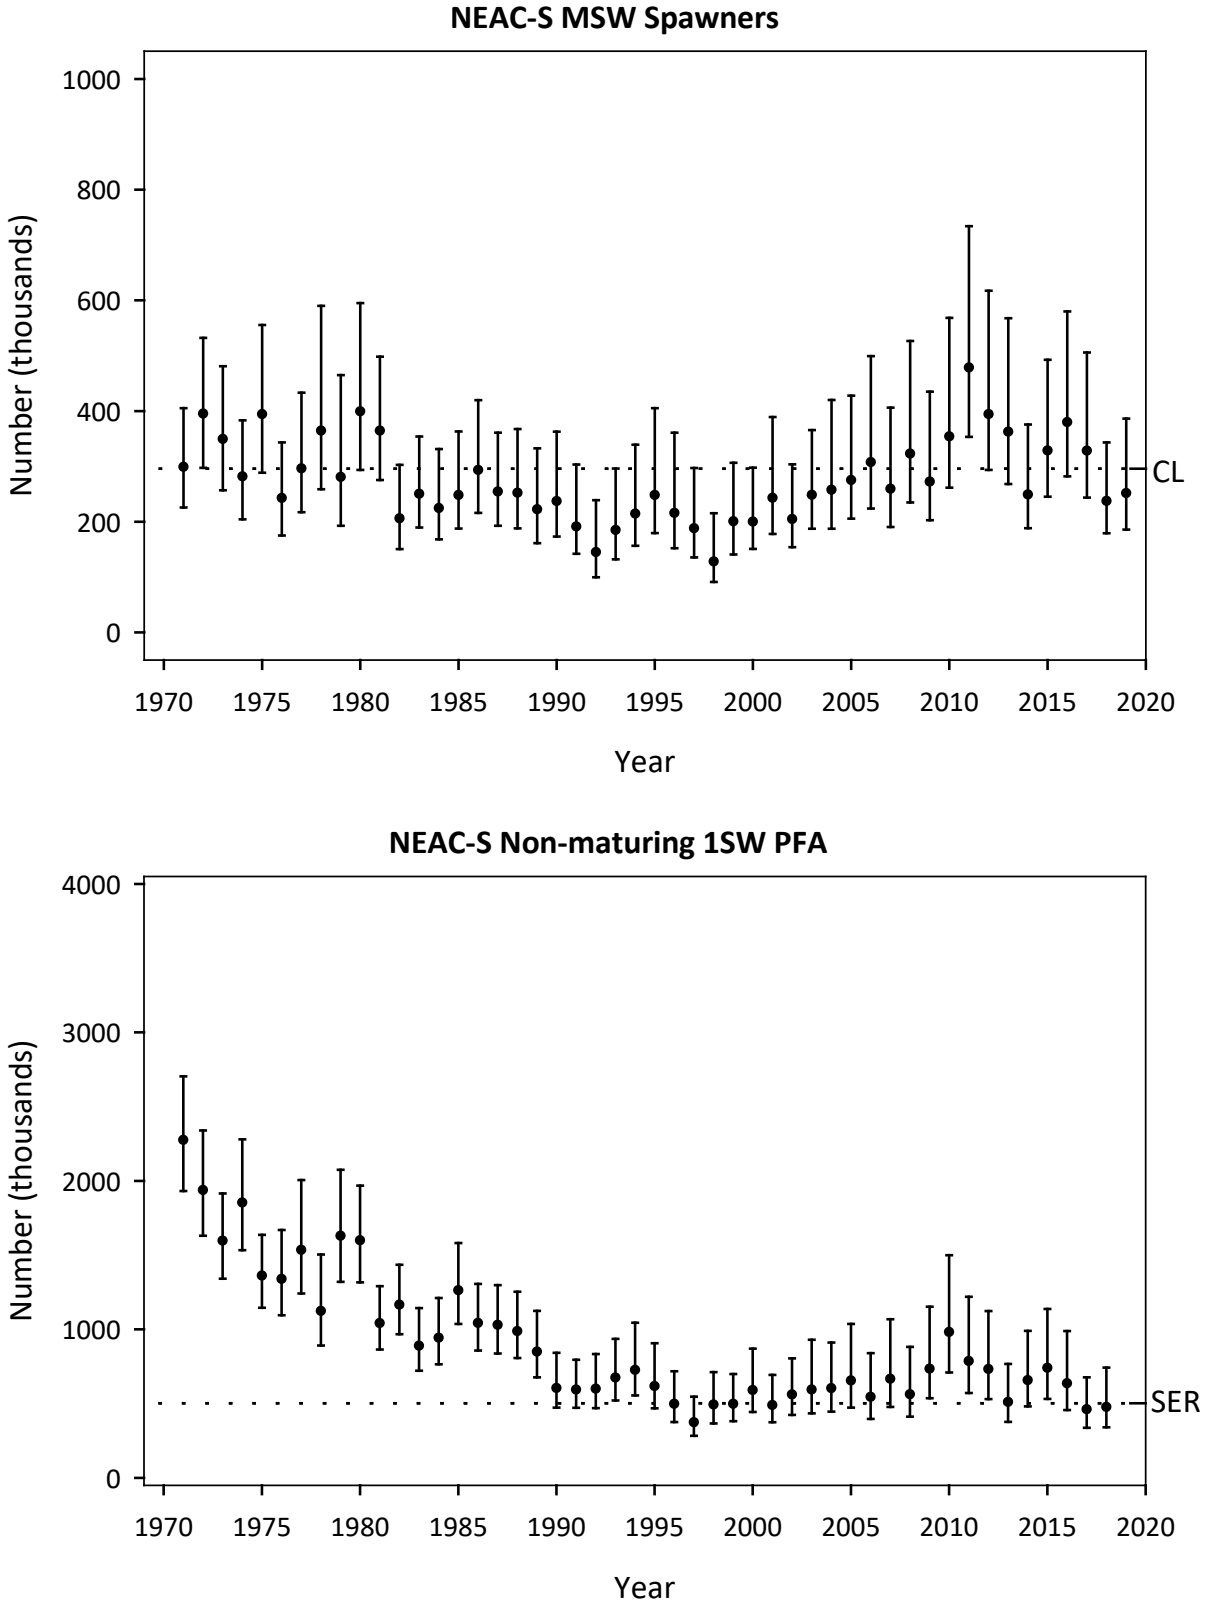

Figure 7 Estimated spawning escapement (upper panel) and PFA (lower panel), and spawning escapement with 90% confidence limits for non-maturing 1SW salmon (MSW spawners) in the Southern NEAC (NEAC–S) stock complex.

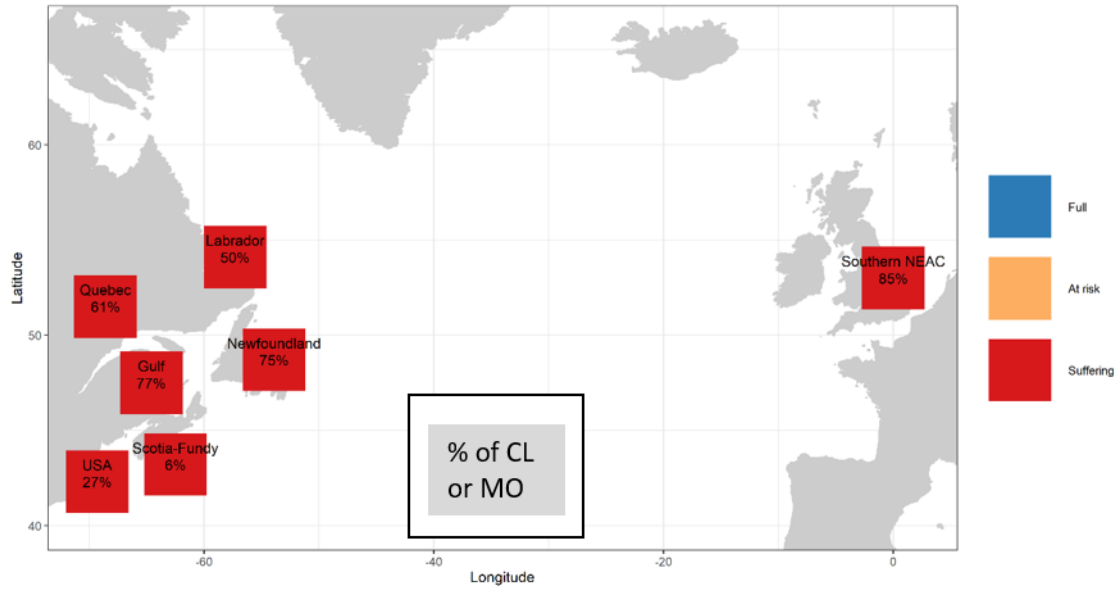

Figure 8 Summary of 2SW (NAC regions) and MSW (Southern NEAC) 2019 median (from the Monte Carlo posterior distributions) spawner estimates in relation to conservation limits (CLs) or management objectives (MO – only for USA and Scotia–Fundy). The colour shading, which in this case is relevant for red only as all stocks in these regions are categorized as suffering reduced reproductive capacity, represents the three ICES stock status designations: full (blue – at full reproductive capacity: the 5th percentile of the spawner estimate is above the CL); at risk (orange – at risk of suffering reduced reproductive capacity: the median spawner estimate is above the CL, but the 5th percentile is below); and suffering (red – suffering reduced reproductive capacity: the median spawner estimate is below the CL).

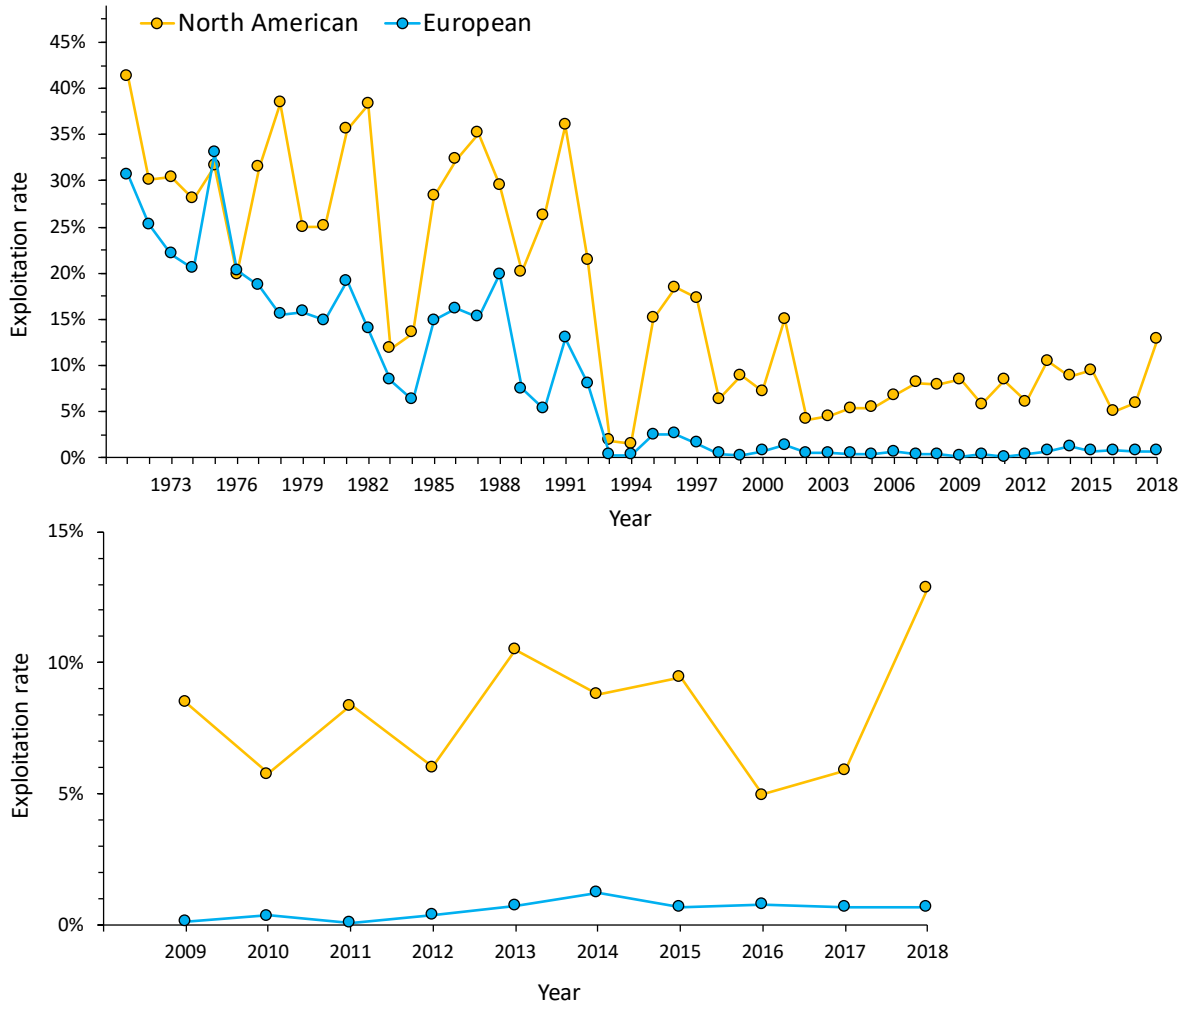

Figure 9 Exploitation rate (%) for NAC 1SW non-maturing and southern NEAC non-maturing Atlantic salmon at West Greenland, 1971–2018 (top) and 2009–2018 (bottom). Exploitation rate estimates are only available to 2018, as 2019 exploitation rates are dependent on 2020 returns.

Annex 1 Glossary of acronyms and abbreviations

1SW *(one-sea-winter).* Maiden adult salmon that has spent one winter at sea.
2SW *(two-sea-winter).* Maiden adult salmon that has spent two winters at sea.
CL, i.e. S_{lim} *(conservation limit).* Demarcation of undesirable stock levels or levels of fishing activity; the ultimate objective when managing stocks and regulating fisheries is to ensure that there is a high probability that undesirable levels are avoided.
ICES (*International Council for the Exploration of the Sea*).
NAC (*North American Commission*). A commission under NASCO.
NAFO (*Northwest Atlantic Fisheries Organization*). NAFO is an intergovernmental fisheries science and management organization that ensures the long-term conservation and sustainable use of fishery resources in the Northwest Atlantic.
NASCO (*North Atlantic Salmon Conservation Organization*).
NEAC (*North-East Atlantic Commission*). A commission under NASCO.
PFA *(pre-fishery abundance).* The numbers of salmon estimated to be alive in the ocean from a particular stock at a specific time.

Annex 2† General considerations

Management plans

The North Atlantic Salmon Conservation Organization (NASCO) has adopted an Action Plan for Application of the Precautionary Approach, which stipulates that management measures should be aimed at maintaining all stocks above their conservation limits (CLs) by the use of management targets. NASCO has adopted the region-specific CLs as limit reference points (S_{lim}); having populations fall below these limits should be avoided with high probability. Within the agreed management plan, a simultaneous risk level (probability) of 75% has been agreed for the provision of catch advice on the stock complexes exploited at West Greenland (non-maturing 1SW fish from North America and Southern NEAC). The management objectives are to meet (a) the Southern NEAC MSW CL, (b) the 2SW CLs for the four northern areas of NAC (Labrador, Newfoundland, Québec, and Gulf) to achieve a 25% increase in returns of 2SW salmon from the average returns in the period 1992–1996 for the Scotia–Fundy region of NAC, and (c) to achieve 2SW adult returns of 4549 fish or greater for the USA region of NAC. A framework of indicators has been developed in support of the multi-annual catch options.

Biology

Atlantic salmon (*Salmo salar*) is an anadromous species found in rivers of countries bordering the North Atlantic. In the Northeast Atlantic area their current distribution extends from northern Portugal to the Pechora River in northwestern Russia and Iceland. In the Northwest Atlantic distribution ranges from the Connecticut River in USA (41.6°N) to the Leaf River in Ungava Bay (Quebec, Canada; 58.8°N). Juveniles migrate to the ocean at ages one to eight years (dependent on latitude) and generally return after one or two years at sea. Long-distance migrations to ocean feeding grounds are known to take place, with adult salmon from both the North American and Northeast Atlantic stocks migrating to West Greenland to feed during their second summer and autumn at sea.

Environmental influence on the stock

Environmental conditions in both freshwater and marine environments have a marked effect on the status of salmon stocks. Across the North Atlantic, a range of problems in the freshwater environment play a significant role in explaining the poor status of stocks. In many cases river damming and habitat deterioration have had a devastating effect on freshwater environmental conditions. In the marine environment, return rates of adult salmon have declined through the 1980s and are now at the lowest levels in the time-series for some stocks, even after closure of marine fisheries. Climatic factors modifying ecosystem conditions, and the impact of predators of salmon at sea, are considered to be the main factors contributing to lower productivity, which is expressed almost entirely in terms of lower marine survival.

Effects of the fisheries on the ecosystem

The current salmon fishery uses nearshore surface gillnets. There is no information on bycatch of other species with this gear. The fisheries probably have no influence, or only a minor influence, on the marine ecosystem.

Quality considerations

Uncertainties in input variables to the stock status and stock forecast models are incorporated in the assessment. Catch reporting at Greenland is considered to be incomplete.

Scientific basis

ICES stock data category	1 (ICES, 2019c).
Assessment type	Run–reconstruction models and Bayesian forecasts, taking into account uncertainties in the data.
Input data	Nominal catches (by sea-age class and continent of origin) for internal use fisheries. Estimates of unreported/illegal catches. Estimates of exploitation rates. Natural mortalities (from earlier assessments).
Discards and bycatch	No salmon discards in the directed salmon fishery.
Indicators	A framework of indicators (FWI) is used to indicate whether a significant change has occurred in the status of stocks in intermediate years where multi-annual management advice applies.
Other information	Advice subject to annual review. Stock annex completed in 2014 and updated in 2019 (ICES, 2019d).
Working group	Working Group on North Atlantic Salmon (WGNAS) (ICES, 2020).
